DICTIONARY
OF
PRACTICAL MEDICINE.

MEDICAL SOCIETY OF LONDON W. 11. CHANDOS ST. CAVENDISH SQ.
Established 1773

COMPRISING

GENERAL PATHOLOGY,

THE NATURE AND TREATMENT OF DISEASES,

MORBID STRUCTURES,

AND

THE DISORDERS ESPECIALLY INCIDENTAL TO CLIMATES, TO THE SEX,
AND TO THE DIFFERENT EPOCHS OF LIFE.

WITH NUMEROUS

PRESCRIPTIONS FOR THE MEDICINES RECOMMENDED;

A CLASSIFICATION OF DISEASES ACCORDING TO PATHOLOGICAL PRINCIPLES;

A COPIOUS BIBLIOGRAPHY, WITH REFERENCES;

AND

AN APPENDIX OF APPROVED FORMULÆ.

THE WHOLE FORMING A LIBRARY OF PATHOLOGY AND PRACTICAL MEDICINE AND
A DIGEST OF MEDICAL LITERATURE.

BY JAMES COPLAND, M.D., F.R.S.

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS;
HONORARY MEMBER OF THE ROYAL ACADEMY OF SCIENCES OF SWEDEN;
OF THE AMERICAN PHILOSOPHICAL SOCIETY;
AND OF THE ROYAL ACADEMY OF MEDICINE OF BELGIUM;
LATELY PRESIDENT OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON;
FORMERLY CONSULTING PHYSICIAN TO QUEEN CHARLOTTE'S LYING-IN HOSPITAL
AND SENIOR PHYSICIAN TO THE SOUTH LONDON DISPENSARY;
CONSULTING, AND LATELY SENIOR, PHYSICIAN TO THE ROYAL INFIRMARY
FOR DISEASES OF CHILDREN; ETC.

"Gladly wolde he lerne and gladly teche."—CHAUCER.

IN THREE VOLUMES.

VOL. III.—PART II.

LONDON
LONGMAN, BROWN, GREEN, LONGMANS, & ROBERTS.
1858

"Read, and fear not thine own understanding; this book will create a clear one in thee; and when thou hast considered thy purchase, thou wilt call the price of it a charity to thyself."

SHIRLEY.

"One caveat, good reader, and then God speed thee!—Do not open it at adventures, and, by reading the broken pieces of two or three lines, judge it; but read it through, and then I beg no pardon if thou dislikest it. Farewell."

THOMAS ADAMS.

"Where there is much desire to learn, there will of necessity be much arguing, much writing, many opinions,— for opinions in good men are but knowledge in the making."

MILTON.

"Uti ratio sine experimentis mendax, ita experientia sine ratione fallax."

BRUNNER.

"Antequam de remediis statuatur, primum constare oportet, quis morbus et quæ morbi causa; alioquin inutilis opera inutile omne consilium."

BAGLIVI.

"It is the great excellence of a writer to put into his book as much as his book will hold."

S. JOHNSON.

"What dire necessities on every hand
Our art, our strength, our fortitude require!
Of foes intestine what a numerous band
Against this little throb of life conspire!
Yet Science can elude their fatal ire
Awhile, and turn aside Death's level'd dart,
Soothe the sharp pang, allay the fever's fire,
And brace the nerves once more, and cheer the heart,
And yet a few soft nights and balmy days impart."

BEATTIE.

"Go, little book, from this my solitude;
I cast thee on the waters,—go thy ways;
And if, as I believe, thy vein be good,
The world will find thee after many days."

SOUTHEY.

PRACTICAL MEDICINE.

Vol. III. Part II.

SCURVY. — Synon.: *Scorbutus*, Sauvages, Vogel, Cullen, &c.: *Scorbutus Nauticus*, Young; — *Porphyra Nautica*, Good; — *Scharbock*, *Skorbut*, Germ.; *Skiorbug*, Dan.; — *Scorbut*, Fr.; — *Scorbuto*, Ital.; — *Scorb*, *Scarbock*, *Skörbut*, *Scorbie*, &c., Saxon, — hence *Scorbutus*, *Scurvy*.

Classif. — *4th Class.* Cachectic Diseases; — *3rd Order.* Impetiginous affections (Cullen); — *3rd Class.* Sanguineous Diseases; — *4th Order.* Cachexies (*Good*). Class. IV. Order IV. (*Author in Preface*).

1. Defin. — *Lassitude, Debility, lowness of spirits, fœtor of the breath and sponginess of the gums, followed by livid sub-cutaneous patches and spots, especially on the lower extremities and roots of the hair, and lastly, by spontaneous hæmorrhages from mucous canals, by contractions and pains of the limbs, and superficial ulcers, &c., the disease proceeding from an alteration of the blood, caused by unwholesome or insufficient food, and by the privation of fresh vegetables and fruit.*

There are few diseases which have excited, or which deserve greater attention than scurvy, not only from medical men, but also from civil authorities and military and naval commanders. The very great prevalence and fatality of the disease during the 15th, the 16th, the 17th, and the 18th centuries, in many communities, in armies, and in fleets, &c.; the causes, both of the prevalence and of the mortality of it, being fully ascertained; the prevention and the counteraction of these causes often being in a great measure in our power; and the treatment in a very large proportion of cases admitting, especially when the causes are removed, of a successful issue, are circumstances which impart both a social and a medical interest to this disease. If we refer to its remarkable prevalence in former times, to the mortality produced by it, to the nature of the causes of its diffusion and severity, it may be justly considered one of the most distressing and fatal pestilences to which the human species is liable.

Even whilst we contemplate the operation of the causes which occasion this malady, the wretchedness and distress which precede the outbreak of it, and the extent of contamination of the circulating fluids, and the disorganisation of the several structures which characterise it; and even while we reflect on the numbers which are liable to suffer from these causes, we feel assured that it is in our power to prevent or to remedy these effects, if we be provided with the ascertained means, and if the causes admit of being removed. Unfortunately, however, these causes are not often removable, even when they are the results, as they often are, of human agency, and are produced by the cupidity and villany of man. Contractors may supply diseased or unwholesome food, both animal and farinaceous, to armies and fleets; and the examiners appointed to ascertain the soundness of provisions may collude with contractors to prevent the detection of the horrible crime until all means of prevention and of remedy are beyond reach. The evils thus produced on an extensive scale may, by similar agencies, be occasioned to a more limited extent in ships or in garrisons; and all preventive and medical means may, with little less culpability, be unprovided, or placed neglectfully beyond the possibility of obtaining them. We have only to refer to the history of our own country at the close of the 17th and the commencement of the 18th centuries, and to the results furnished by the wars in Ireland and in the Low Countries, and by the diseases in our armies and fleets at these periods, both for an estimate of the ravages of scurvy and its associated maladies, and for an account of the criminal agencies concerned in their production.

The comparatively rare occurrence of scurvy in this country, in its fleets and armies, and in its mercantile navy, during the last quarter of the 18th century and the first quarter of the present century, had in some degree diverted the attention of public authorities from the causes and the prevention of this very important, and, on many occasions, pestilential malady. As respects the fleets of this country, the favourable results observed during many years were attributable to due attention having been directed to the means of prevention — to the avoidance, as far as possible, of exposure to cold and humidity, to greater care in preserving the water in a pure state, to a more liberal supply, and to a more careful examination of provisions. Unfortunately, however, in very recent times, circumstances and causes favourable to the prevalence of the disease, especially in our armies in the East, occurred; and, notwithstanding the shorter duration of voyages of fleets and trading vessels, the want of attention in too many instances to prophylactic measures produced the usual bad consequences. As on almost every occasion for hygeienic measures, and in every disease, so in this, the most salutary and the most efficient means of prevention have been ascertained and promulgated by medical men, who, notwithstanding their admitted philanthropy, were not only unrewarded, but illiberally treated, by governments and by the public generally.

The causes of scurvy, and the means of preventing the evils produced by them, when the causes are neither very complicated nor very formidable, have been long ascertained, and have generally been rendered practically available. But, unfortunately, the nature and the sources of the causes have been such as often to preclude both prevention and cure; and the intensity and combination of causes have often not only spread the disease, but also imparted to it more malignant and more fatal characters. — The simpler states of scurvy, arising from less severe and more common causes, are converted into a most diffused and irremediable pestilence by increased intensity of the causes, especially by insufficient and unwholesome food, by foul waters, by overcrowding and imperfect ventilation, by cold and humidity, by excessive labour in trenches, fortifications and unhealthy localities, by despondency and want of sleep, more especially when armies, fleets, and besieged towns are subjected to these miseries. In these circumstances, amongst numerous cases of fully and rapidly developed scurvy, others closely allied to them in their nature, but even more fatal in their tendencies, especially scorbutic dysentery, putro-adynamic fever, and hospital gangrene, soon make their appearance, increase in numbers, and very remarkably augment the mortality. If the separation of the sick from the healthy, and if due ventilation be not enforced as soon as the occurrences take place, the malignancy and danger of these diseases are further increased by the generation of infectious emanations, which often remarkably accelerate a fatal issue. This is no overcharged picture, for whoever of those living at the middle of this century who have had an opportunity of observing the maladies produced in and by armies and besieged cities, &c., more especially on the continent of Europe, in the early part of the present century, must admit that it is impossible to portray the amount of suffering and of wretchedness, of disease and deaths proceeding from these causes. Similar results will follow these causes again, and whenever wars, unhealthy encampments, insufficiently supplied commissariats, the criminality of contractors, imperfect means of preventing and of curing disease, crowded and improperly placed hospitals, &c., combine to develope them; and they will appear to an extent and with a fatality co-ordinate with the intensity and the combination of these causes — causes which have been productive of a very much greater sacrifice of human lives, and with much greater sufferings, than all the battles and sieges which have been recorded.

2. I. Historical Sketch.— Some writers have supposed, with Sennertus, Mead, and Milman, that scurvy was known to the ancients, whilst others have believed, with Friend, that there is nothing to be found in their writings to warrant this supposition. Hippocrates, in mentioning enlargement of the spleen — σπλὴν μέγας — notices but one symptom which is applicable to scurvy, and that is ulceration of the legs; and, in describing Convolvulus Sanguineus — Εἰλεὸς αἱματίτης — he adduces the dark discoloration of the skin, the eruption of ulcers on the legs, and the difficulty of walking, as more particularly distinguishing it. But these remarks are insufficient to show that he was actually acquainted with true scurvy. It has been supposed that the disease, with which Pliny states the army of Cæsar Germanicus to have been afflicted after a long encampment in Germany beyond the Rhine, near the sea-coast, and which was ascribed to the water which was drank, was that now under consideration. He states, that "the teeth dropped out, and the knees became paralytic. The physicians called the malady *Stomacace* and *Sceletyrbe*. They discovered a remedy against it, viz. *Herba Britannica*." What this plant, of which Pliny adds a very short and imperfect description, actually was has not been shown by his commentators. Subsequent ancient writers, not even the Arabians, have furnished nothing in addition to what I have now adduced.

3. The earliest account of scurvy is that given by the Sieur Joinville, as it appeared in 1260, in the army of Louis IX. in Egypt, owing to the nature and scarcity of the food, and the scarcity of water. The next notice taken of it is by Fabricius, who states that it was very prevalent and fatal in Misnia, during 1486. As soon as long voyages were undertaken, scurvy appeared in an unmistakeable form. During the voyage of Vasco de Gama, who first made the passage to the East Indies, by the Cape of Good Hope, more than one hundred of his men out of one hundred and sixty died of this malady. The History of Portuguese discoveries, by W. Lopes de Castennada contains the relation of this voyage, which furnished the first account of this disease as it occurred at sea.

4. That scurvy was not then, nor for some time afterwards, known, is evident from the account given by Cartier of his second voyage to Newfoundland in 1535. After mentioning the characteristic symptoms, he adds that, "about the middle of February, of a hundred and ten people there were not ten whole." "Eight were already dead, and more than fifty sick, seemingly past all hopes of recovery. This malady being unknown to us, the body of one of our men was opened to see if by any means possible the occasion of it might be discovered, and the rest of us preserved. But in such sort did the calamity increase, that there were not now above three sound men left. Twenty-five of our best men died; and all the rest were so ill, that we thought they would never recover again. When it pleased God to send us the knowledge of a remedy for our health and recovery." The remedy was a decoction of the leaves and bark of a tree, which was called by the natives *ameda* or *hamuda*, and which has been considered to have been a species of spruce-fir.

5. Dr. Lind states, that the name of this disease

advances, they are not only much disordered, but are much more frequent and very offensive. Diarrhœa and colicky pains often supervene; and, with more or less attendant hæmorrhage, rapidly sink the patient at this stage. Under certain circumstances, the disease passes into a state of scorbutic dysentery, or dysentery and scorbutus supervene upon each other, and thus become associated, as shown when treating of DYSENTERY (*see that art.* § 39. *et seq.*). The *urine* is scanty and high-coloured (see § 20.).

14. The *pulse* is often little affected at an early stage; but is more generally slower and feebler than in health; but, in more advanced cases, or when the malady is associated with some degree of asthenic or sub-inflammation in the seats of effusion, the pulse is often remarkably frequent as well as small or weak. When the pulse is slow and feeble, the patient is often chilly, the surface cool, and the temperature of the body lower than natural. This state of the disease was called the *cold scurvy* by the earlier writers. When much swelling and hardness, with pain, is occasioned by effusion in the connecting cellular tissue, or even below the periosteum, the pulse is generally frequent, varying from 100 to 120 in a minute, probably owing to some degree of inflammatory irritation produced by the effused matters in these situations, as indicated by the great tenderness which always is present. This state of febrile action gave rise to the distinction of *hot scurvy* according to various authors.

15. The *tongue* is generally clean and pale, but commonly broad, flabby, and indented at its edges by the teeth. The insides of the cheeks and lips are pallid, and contrast remarkably with the appearance of the gums. *Thirst* is not much complained of, unless in the more febrile state of the disease, or when the supply of fluids is scanty. The *appetite* is not impaired. It may be even greater than in health; and digestion is not very manifestly impaired. *Sleep* is not deficient, unless at a far advanced stage, when wakefulness or disturbed sleep is experienced. The *mental faculties* are not impaired, although the spirits are generally more or less dejected, and anxious; but towards a fatal issue the patient becomes indifferent and torpid. The memory is generally unimpaired; but the eye-sight is occasionally weakened.

16. As the disease approaches an unfavourable issue the *breathing* becomes remarkably frequent, and the *dyspnœa* extreme. The patient coughs, and expectorates a frothy mucus, sometimes tinged with dark blood. The chest was generally every where resonant on percussion; the respiratory murmur was loud and distinct; and the sounds of the heart were loud and extensive, but unaccompanied by any morbid bruit in six cases examined by Dr. BUDD. In the most advanced states of scurvy not only may ulcers and injuries or wounds which have healed up for many years break out afresh, but old and well-united fractures may become disunited. The tendency to *swoon* in the most severe cases is sometimes so great that the slightest motion, or the erect posture, or even any trifling exertion, may be followed by fatal syncope. It is stated in the account of Lord ANSON's voyage, that many of the men, although confined to their hammocks, ate and drank heartily, were cheerful, and talked with much seeming vigour, and in a strong tone of voice; and yet, on their being the least moved, although it was only from one part of the ship to another, and that in their hammocks, they have immediately expired; and others who have confided in their seeming strength, and have resolved to get out of their hammocks, have died before they could reach the deck. And it was no uncommon thing for those who could do some kind of duty, and walk the deck, to drop down dead in an instant, on any endeavours to act with their utmost vigour.

17. Emaciation is not necessarily a phenomenon of the disease, unless there has actually been considerable privation of food; but it is occasionally observed, and anæmia is not infrequent. Dr. BUDD observes that, although there is a remarkable tendency to the breaking out of old ulcers or wounds long previously healed, yet there is very little disposition to the occurrence of bed-sores from pressure. The separation of the epiphyses from bones has been mentioned by some writers, as having occurred in children attacked by this malady, but it has not been often observed in adults, or, if observed, not mentioned by many writers.

18. *Scorbutic ulcers* exude a thin, fœtid, sanious fluid, instead of pus. Their edges are of a livid colour, and as if puffed up; a coagulum soon forms on their surfaces, which is separated or wiped away with difficulty. The parts underneath it are soft, spongy, or putrid. When this coagulum is removed, the same change again occurs after a few hours, forming a soft, bloody, fungus, resembling boiled bullock's liver. This fungus exudation, Dr. LIND states, sometimes rises in a night's time to a great size, and, although cut off, in which case a plentiful hæmorrhage generally ensues, at the next dressing is as large as ever.

19. ii. THE CHEMICAL ANALYSES OF THE BLOOD AND URINE in scurvy have been few, and even these unsatisfactory. It is manifest that the states of the blood and of the excretions in this disease will depend much upon the treatment adopted, and upon the time during which the treatment has preceded the analysis.—*A.* SIMON's "Animal Chemistry" furnishes no information as to the *blood* in scurvy; but Dr. DAY, in his additions to the work, states that Mr. BUSK, in three well-marked cases of scurvy, found the composition of the blood as follows; comparing the scorbutic blood with the healthy according to his analysis of the latter:—

	1st Case.	2nd Case.	3rd Case.	4th. Heal. blood. (*Busk*).
Water - - -	849·9	835·9	846·2	788·8
Solid constituents -	150·1	164·1	153·8	211·2
Fibrin - - -	6·5	4·5	5·9	3·3
Albumen - -	84·0	76·6	74·2	67·2
Blood-corpuscles -	47·8	72·3	60·7	133·7
Salts - - -	9·5	11·5	10·9	6·8

Although the fibrin appears to be increased, its vital cohesion is evidently impaired; and the albumen is certainly altered in quality, although the alteration is not shown by chemical analysis.

20. *B.* The *urine* in scurvy is commonly of a dark, reddish brown, and sometimes of an almost black colour. Although it is slightly acid as it is evacuated, it very soon becomes alkaline, and emits a strong and disagreeable ammoniacal odour. Blood is often discharged with the urine, and the urine then assumes a dark reddish-brown colour, in consequence of the presence of hæmatoglobulin;

in this case it developes hydrosulphate of ammonia, and soon becomes putrid. Dr. SIMON examined the urine in three cases of scurvy in SCHÖNLEIN's clinical wards — two men and one woman. The urine was very similar in these three cases, in its physical characters. It was scanty, and of a deep, dark-brown colour; after standing a few hours it emitted a disagreeable ammoniacal odour. The three specimens resembled each other, and were found to approximate the chemical characters of the urine in typhus. The urea was less than in healthy urine, not exceeding 25 30ths of the solid residue. The fixed salts were diminished in the two male cases, being 14-18ths of the solid residue; but in the female they were 27, or a little above the normal average (25). The uric acid was slightly above the healthy standard in all, being from 1 to 3 of the solid residue.

21. iii. APPEARANCES ON DISSECTION. — Scurvy at the present day seldom proves fatal, unless in ships, or in besieged towns, where opportunities of minutely examining the bodies after death are rarely enjoyed; and the observations of early writers on this subject are generally devoid of precision, and the necessary details. The best account of the appearances after death has been furnished by Dr. BUDD, from the cases which were brought to the *Dreadnought* Hospital Ship. He states, "The general inferences to be drawn from preceding facts are, that in the *inspection* of the bodies of persons who die of scurvy, the chief indications of that disease are met with in the colour of the skin, in the state of the gums, and in the presence of fibrinous effusions, and of ecchymoses, or effusions of blood. These effusions occur most frequently in the skin, in the subcutaneous cellular tissue, and between the muscles of the lower extremities, between the periosteum and bones of the lower extremities and of the jaws; and in the peritoneal coat, and in the muscular and mucous coats of the intestinal canal. The numerous traces of hæmorrhage observed in the coats of the intestines are in accordance with the frequency with which scorbutic persons pass blood by stool."

22. The slight effusions of blood between the periosteum and bone do not destroy the muscular connections between these parts, so that the latter does not generally present further alteration. Beyond a paleness of tissue, there is no change characteristic of scurvy observable in the brain. The organs of respiration, the heart and large blood-vessels, the glandular system and the bones, presented no remarkable changes in the cases inspected by Dr. BUDD. His observations furnished him with no direct information respecting the *blood*, except that it is deficient in red particles; that it does not impart a stain to the lining membrane of the heart or vessels; and that it has not lost the property of coagulating. The change observed in the skin and in the complexion is to be ascribed to the alteration of the blood, and the hæmorrhages doubtless proceed, at least in part, also from this alteration. Former writers have noticed more or less of a fluid or dissolved condition of the blood, and a soft, flabby state of the *heart;* this latter change accounting for the swooning and fatal deliquium sometimes occurring in the more extreme cases. The *liver* has been found pale, or of a pale buff colour, or of a nutmeg appearance; and the *bile* in the gall-bladder of a pale or yellowish colour. The *spleen* is generally soft, of a plum colour, and often more or less enlarged. The *lungs* are sometimes œdematous, especially in their more depending parts. The *kidneys* and urinary passages seldom present any change in the uncomplicated states of the disease.

23. According to the descriptions of POUPART, LIND, and others, the blood discharged from the mucous canals during life, as well as that found in the cavities of the heart and vessels after death, was remarkably altered, fluid, broken down, and presented more or less of a greenish-black hue. The spleen was generally much enlarged, and so soft as to break down on being handled. Adhesions often existed between the costal and pulmonic pleura, and sometimes dirty serous effusions were found in the pleural cavities. Black, corrupted blood was generally effused between the muscles, or infiltrated between their fasciculi, and under the skin and periosteum; and the auricles were remarkably distended by coagulated blood, in those who died suddenly. In young subjects the epiphyses were loosened from the shafts of the long bones, and the ribs had separated from their cartilages. In some, the glands of the mesentery were more or less enlarged. The kidneys were occasionally altered. The alterations found in the bones, especially those now mentioned, most probably arose from the effusion of blood between the periosteum and osseous structure, and from the consequent destruction of the vessels of the former which nourish the latter.

24. iv. COMPLICATIONS, &c. — Much of the diversity observed in the symptoms and progress of scurvy, as well as in the appearances after death, depends upon the nature of the food, or of the privations causing the malady, and upon antecedent, concurrent, or intercurrent disease; for, as will be shown in the sequel, although the privation of fresh vegetables and fruit is mainly productive of it, still much is owing to the food upon which the patient has been living up to the time of his attack and during its progress. The diseases which commonly precede and favour the appearance of scurvy are agues and remittent fevers, enlargement of the spleen or liver, rheumatism, dysentery or chronic diarrhœa; and either of these may complicate, in a more or less evident manner, the scorbutic state, especially in its more chronic form, or may appear as an intercurrent malady. These complications are most apt to occur in warm or temperate climates, and wherever malaria is present; and probably the association with rheumatism is most common in colder regions and seasons. When they do appear they are readily recognised when the physician is alive to the probability of their association, and when the causes, on which they chiefly depend, are observed to be in operation. The supervention of scurvy upon ague, or upon enlargements of the spleen, or upon affections of the bowels, is not infrequent, especially in the winter and spring months, when fresh vegetables and fruits have become scarce, and when cold, humidity, and these diseases have predisposed the frame to this malady; and it was certainly much more common in former ages, before potatoes came into general use.

25. *The complication of Scurvy with Dysentery* was the most prevalent and fatal disease during

the Burmese war, and was entirely owing to the nature of the food in connection with malaria and bad water. But it is unnecessary to add, at this place, to what I have stated when treating of the *forms and complications of* DYSENTERY (see § 39. *et seq.*)—Although *rheumatism* is undoubtedly in some cases, and at certain seasons, occasionally associated with scurvy, still the pains, which are most commonly attendant upon the latter, are rather to be imputed to the infiltrations of blood which take place between the muscular fasciculi and under the periosteum, than to any rheumatic complication. A moderate attention to the matter will be sufficient to distinguish the nature of the case; as well as the existence of enlargement of the spleen, and the connection of the disease with ague.

26. Persons labouring under scurvy are very liable, when exposed to cold and humidity, to experience severe attacks of *pleurisy*, or of *pericarditis* or of *peripneumonia*, or of *bronchitis*, which may carry off the patient in a short time, without materially influencing the symptoms of scurvy. In these cases, the dyspnœa, cough, and difficulty of expectorating become urgent; the expectoration varying with the state of pectoral disease, from a slight mucous frothy matter, to a dirty brown, or dark-red, or sanious substance. Effusion into the pleural cavities, or effusion into the air-cells and small bronchi, and splenification of the substance of the lung, ultimately hasten or occasion a fatal issue. In rarer instances changes in the *kidneys*, which I have ascribed to cachectic inflammation of the secreting structure of these organs (see art. KIDNEYS, § 80. *et seq.*) supervene, and, by embarrassing the functions of these organs, superinduce dropsy upon the scorbutic disease, and thereby occasion or accelerate an unfavourable termination.

27. III. DIAGNOSIS.—Of the numerous writers who preceded LIND, very few pointed out with due accuracy the diagnostic characters of scurvy, or distinguished sufficiently between this disease and *malignant or putrid fevers*. In many circumstances and on many occasions, some of which I have myself witnessed, it is difficult to determine as to the presence of scurvy or of putrid fever, at first sight, or until a more patient and close observation has shown the difference, so insensibly or gradually, in such circumstances, some of which I observed in Germany and France after the last war, does the one malady approach the characters of the other. In Ireland, in 1847, owing to the failure of the potato-crop and general misery, scurvy was intimately associated with putro-adynamic fever, and it was most difficult to distinguish between them, or to say which was the primary malady. The same observations equally apply to *purpura*, which often arises from similar causes to those producing scurvy, and is more or less closely allied to, although generally distinguished from, scurvy, the more extreme points of difference between the two having been laid hold of as diagnostic characters, whilst the closest resemblances have been kept out of view. It will be more just, more conducive, moreover, to accurate pathological views, and certainly tend more to the adoption of sound indications and means of cure, to look closely at diseases as they occur in practice, to consider both alliances and differences, and to proceed in our treatment on the comprehensive basis thereby furnished us.

28. Circumstances have occurred, and may occur again, in which certain of the causes of malignant fever, as a confined impure air, crowding of numbers into a small and ill-ventilated space, &c., have come into operation, in connection with the causes of scurvy, especially a deficiency or want of fresh vegetables and fruit, and have given rise either to the petechial or putro-adynamic form of fever, or to a state of febrile scurvy, or to a disease, in which the symptoms of either the one or the other predominated, according as the causes of either prevailed. In attempting to distinguish between these diseases, or to determine the existence of either, the discriminating physician will be guided by the slow and gradual, or the rapid accession of the symptoms; by the states of the skin, of the gums, and of the teeth; of the general surface, and particularly of the lower extremities; by the discolouration and other changes there observed; by the presence or absence of complete prostration and of other febrile phenomena; by the acuteness or intensity and duration of the malady; by the appetite and function of digestion; by the inability or capability of leaving the bed; and by the presence or absence of contractions of the lower extremities, or of hardness, swelling and livid patches or ulcers in these situations.

29. In distinguishing also between scurvy and *Purpura*, the presence or absence of the majority of the above symptoms, and more especially the states of the gums and teeth, the swellings, indurations, livid blotches, œdema of, or the fungous ulcers on, the extremities; the contractions of the joints; and various associated phenomena, will guide the physician to a correct diagnosis, and whilst they indicate with due precision the existence of either the one or the other, will at the same time point out the close alliance between both as to their causes and their natures. (See PURPURA (§ 23.).

30. IV. THE PROGNOSIS OF SCURVY. — Before the disease is advanced so far as to present contractions, indurated swellings or fungous ulcers on the extremities; or hæmorrhages from mucous canals; or swoonings upon assuming the erect posture or on slight exertion, a speedy recovery will generally follow the use of the means about to be recommended; but when the malady is thus far advanced, although the same means will often save the patient, they may also fail; and this unfavourable result is the more likely to ensue if, with these symptoms, the patient complains of dyspnœa, and oppression at the chest; if his respiration and pulse be very frequent; if there be any pulmonary, pleuritic or dysenteric complication; if dropsical effusions or albuminous urine supervene; if the spleen be much enlarged; and if hæmorrhages from the bowels be copious, then great danger may be apprehended, and with still greater reason, if the adoption of a suitable diet and remedies is not soon followed by any amendment.

31. In cases which present not the extreme symptoms characteristic of scurvy, and are nevertheless unamenable to the usual scorbutic remedies, some complication should be looked for and ascertained, as this most probably either retards or prevents the efficacy of such means, or the disease partakes, owing to the causes above noticed (§ 28.), more or less of the characters of putro-

adynamic or petechial fever — possesses the intermediate form already mentioned (§ 27.), and requires an appropriate method of treatment. I am persuaded, that the instances of scurvy which have been adduced of the failure of these remedies, have either been the severer, or pulmonic, pleuritic, pericardiac, dysenteric, or dropsical complications of the distemper, or those intermediate states of disease now alluded to.

32. V. Causes of Scurvy. — The causes of scurvy were only partially known until a comparatively recent period; for the disease was often ascribed to one only of the causes, and that a predisposing cause; and even now, when the chief causes have been duly recognised, others which either predispose the frame to their operation, or concur with them, and aid or determine their effects are too generally overlooked, and their influence in modifying the malady, or in delaying or preventing the beneficial operation of the means employed, is altogether neglected, or even unknown. It has been fully ascertained that several of the causes to which scurvy was formerly imputed are not really the exciting or efficient causes of this malady; but their influence as predisposing, concurring, or determining causes should not be denied, although they cannot take the highest rank in causation, or because they have been pushed from the position formerly assigned them, by others of much greater influence.

33. i. Predisposing causes. — Several of these causes were formerly believed to have had the chief share in the production of scurvy; but they are now more clearly proved to perform a less important part; but this part they fill in the causation not only of this malady, but also of dysentery, putro-adynamic fever, purpura, and probably of other diseases.—*A.* Much importance was attached formerly to living on *salt provisions*; and as this disease most frequently and certainly appeared in ships provisioned with salted meats chiefly, so it was inferred that these were the causes of its occurrence. That salted meats are not more productive of scurvy than fresh meats, or at least not much more so, is shown by the prevalence of the malady, in the spring of 1720, in an army which Kramer stated to have enjoyed an abundance of fresh meat at a low price; in the Russian armies, in 1736, which were similarly circumstanced; in the French prisoners, at the middle of last century, who had no salt provisions; and in the regiments at the Cape, in 1836, that enjoyed an abundance of fresh meat.

34. From these and other facts it may be inferred, that scurvy may appear even amongst those who have a sufficient supply of fresh meats, if there be a prolonged deficiency at the same time of succulent vegetables and fruits. Nevertheless, the question remains, are salted meats more favourable to the supervention of scurvy than fresh meats? I believe, after having paid some attention to the matter, that recently salted or uninjured salt meats, if they have been of a good and healthy description, and quite fresh when salted, are not materially more productive of scurvy than fresh meats; but whilst the quality of the latter is generally manifest, that of the former is not always so evident. The salted provisions supplied to ships have frequently been long cured, even before they are received on board, and are so often of the most inferior and unwholesome character, as to account in great measure for the appearance of cachectic maladies in those who live upon them. It was notorious, during Queen Anne's wars, that, owing chiefly to collusion between the heads of the commissariat or others in power and the contractors, and even in more recent times, that the salted provisions supplied to the navy and army often consisted not only of long or imperfectly cured meats, but also of the flesh of animals which had died of disease; that horse-flesh was often placed in casks of beef; and that similar villanous acts were not confined to salted provisions, but extended also to the flour and biscuits supplied to these services, both of these having been adulterated, and the latter mouldy and swarming in maggots and weevils. Owing to this cause, as shown by some medical writers of the day, a much greater number of human lives were lost from scurvy, scorbutic dysentery, and putro-adynamic fever—by diseases caused by the unwholesomeness of the provisions — than from all other diseases, and from naval and military actions, sieges, and other causes combined.*

35. Not only were both salted and farinaceous provisions frequently deleterious, but the supply also was insufficient to both army and navy, up to the mutiny at the Nore, the causes of which were generally misrepresented by those in power, and misunderstood or glozed over by historians. In times more recent, acts similar to the above have been perpetrated in more places than one. The returns made to the Medical Boards in India by the medical officers, and which are preserved at the India House, are full of complaints as to the unwholesome nature of the provisions supplied to the army in the Burmese war; even the rice having been either unripe or damaged. The remarkable prevalence of scorbutic dysentery, and low fever among the troops in that war, was ascribed chiefly to this cause; the mortality continuing great until more wholesome provisions were procured. But it was not only in the public services — in fleets, armies, and transport vessels — that these enormities were practised, trading vessels, emigrant ships, &c., were sometimes, and are occasionally up to the present day, supplied with the cheaper kinds of Irish provisions, which are frequently of a similar kind to that above described; and to this circumstance in part, and to others about to be noticed, should be ascribed the scurvy and fever so frequently breaking out in ships after their provisions have been used sufficiently long to produce their effects. To the unwholesomeness and nature of the food, and to the state of the water, even independently of the want of fresh vegetables and fruit, the diversity of characters presented by scurvy and fever in ships, armies, prisons, &c., is in great measure to be imputed, as well as the want of success in treating these diseases by the more usual remedies, or by those more generally found efficacious under other circumstances, — the same causes not merely

---

* From a tolerably extensive field of observation in various parts of Europe and within the tropics, between the years 1815 and 1819 inclusive, I can state, that, of the various kinds of unwholesome cured meats, pork is perhaps the most injurious: especially when it has been imperfectly salted, or too long kept; and, more particularly if it have been coarsely fed, or diseased, or not cured immediately upon being killed: scorbutic and other forms of dysentery generally resulting.

predisposing to these forms of disease, but actually producing them, and giving them their distinctive features.

36. Much of the mischief observed in those who had lived long on salt provisions was formerly, and still is, by many imputed to the salt by which these are cured, or at least to the state of the provisions; and by others to the supposition that salted meats are not so nutritious as fresh. But, when these provisions have been from the first wholesome and good, have been salted while quite fresh, and have not been afterwards kept so long as to produce any sensible or unpleasant change, they may then be considered as having had no further share in the production of scurvy, even although it should have appeared during the use of such provisions, than that they have constituted the chief or only food, to the neglect of other articles requisite to correct the effects of so exclusive a diet, such as fresh vegetables and fruits. On this subject, Dr. **Budd** justly remarks, that "the circumstances showing that scurvy may prevail to a frightful extent among persons living solely on fresh meat; that persons who, from the nature of their occupations, are continually absorbing saline particles, are exempt from scurvy; that scurvy is not brought on by the use of sea-water, which may be drunk with impunity, even by scorbutic people; and that the disease may be prevented for any length of time in persons who subsist on salt provisions, and can be readily cured, even in those who continue the use of them, are sufficient to justify the conclusion, that salt has no share whatever in producing it." (p. 65.) To this statement I would merely add, that the salt conceals, and partly corrects, the sensibly noxious properties of previously tainted, diseased, or otherwise unwholesome meats, and hence meats of this description, when salted, are more readily, and perhaps less injuriously, partaken of, and, moreover, have not their injurious nature made so manifest, or even suspected, as if an attempt to use them in their fresh state were made.

37. *B.* Next to the state of *meat provisions*, that of *farinaceous food* supplied to ships, armies, &c., as predisposing to, or even as producing scurvy, may be noticed. In various countries in the East, where little or no animal provision is used, scurvy has nevertheless appeared, and has been ascribed, with sufficient reason, not so much to deficiency of the amount, as to the unwholesome nature, of the food, whether rice, Indian corn, &c., which often have been damaged, unripe, mouldy, or too long kept. The flour, biscuits and other farinaceous articles, supplied by contract or otherwise to the public services, and to trading vessels, were formerly, on many occasions, similarly damaged and unwholesome, or became so after having been kept for some time; and contributed their share towards the production of scurvy, fevers, and even to visceral disease. That these articles of food have actually been productive of these maladies, was demonstrated by the occurrences in the Burmese war; native Indian regiments subsisting entirely on rice and other farinaceous articles, which in that war was more or less damaged and unwholesome, having been universally attacked with scurvy and scorbutic dysentery.

38. *C.* The *water* also, with which ships of war and trading vessels were supplied for long voyages, having been kept in wooden casks, the use of iron tanks for this purpose being of recent date, the water became offensive and unwholesome, on many occasions so much so as to be nauseous and to require the addition of spirits to prevent its more immediate ill effects. The effects of marsh water in causing bowel complaints and enlargements of the spleen and liver, are well known to many who have possessed powers of observation in connection with the requisite opportunities. But I can say from personal observation, that water, long kept in wooden casks, however well these casks may have been charred, as they sometimes are on their insides, become even more deleterious to health, and much more offensive to the senses than any water taken from marsh-grounds or land-tanks, much, however, depending upon the state of the water when filled into the casks. The greater attention now paid to the supply, state, and preservation of water in the public services, and in trading vessels, is one of the chief causes of the less frequent appearance of disease in them, and more especially of scurvy and allied maladies.

39. *D. Cold and humidity* have long been considered as very influential in favouring the occurrence of scurvy. That these causes are of some importance, I can assert, although Dr. **Budd** strongly doubts their influence. But he has not viewed them in a proper light. He remarks that "the merchant seamen who enter the port of London, affected with scurvy, come almost exclusively from Mauritius, India, Ceylon, or China; and have consequently been in no higher latitude than that of the Cape." But he overlooks the circumstance that those voyages are long, and that the men have been living long upon cured meats, without a due supply of fresh fruits and vegetables; whilst most other vessels arriving at the port of London have had short voyages, they coming from much nearer countries, and consequently a sufficient period for the development of scurvy in them has not elapsed. It is not, however, the cold and moisture depending upon climate, or even upon weather, that are so influential in favouring the development of scurvy, as the cold and humidity arising from daily, and even twice daily, washing and scrubbing the decks, formerly and even still so much in use, to the neglect of dry-scrubbing and cleansing. The evaporation from the wet decks during day and night, consequent upon frequent washings during fine and dry weather, and the wet and humidity of body-clothes, bed-clothes, and hammocks, produced by these washings, and during foul or stormy weather, are the forms of cold and humidity which, on ship-board, predispose to scurvy, and more directly produce the several forms of rheumatism, chiefly by suppressing the cutaneous functions, by reducing nervous power, and thereby causing the accumulation of those excrementitious matters, the retention of which occasions these maladies. All the most experienced writers on scurvy have remarked the suppression of the cutaneous functions previously to the appearance of, and during the progress of scurvy, and I have no doubt of the fact from my more limited observation.

40. *E. Impure air* has been considered by some writers as predisposing, more or less, to the appearance of scurvy. The testimony of **Lind**, **Trotter**,

and BLANE, most experienced physicians, is opposed to the opinion, that it has any influence either in the production, or on the course of this malady. That the influence is not very remarkable, may be admitted; but that this cause is not altogether without effect cannot be denied, especially in modifying or altogether changing the characters of the disease, when conjoined with those causes which more directly and commonly produce scurvy. It was observed in the American squadron, in 1846, that scurvy was most severe in vessels which were the worst ventilated.

41. *F. Several other diseases* predispose the frame to the appearance of scurvy; and although the predisposing influence has been attributed to the debility produced by those diseases, yet I believe that it is not the debility alone which predisposes, but more especially the nature of the malady. Agues, remittent fevers, enlargement of the spleen, and rheumatism, and previous disorder of the digestive organs, especially the former, have been generally considered by medical writers as more or less influential in the production of scurvy. The previously impaired assimilation and nutrition, and the consequent state of the blood, in connection with exhausted organic nervous energy, readily account for the readiness with which scurvy supervenes upon those maladies when its causes are in operation.

42. *G. The state of the mind* is influential both in predisposing to, and warding off scurvy; the depressing passions favouring the appearance, and the exciting emotions preventing or delaying the occurrence of the malady. Disappointed expectations; anxiety; hope deferred; longings to return to more desired scenes; prolonged confinement; a want of exciting, amusing, and exhilarating occupations; breathing the same kind of air, in the same locality; a monotonous and unexciting course of existence; losses of relations and friends, and extinction of those hopes or expectations which render privations endurable, — all have their influence in predisposing the body to scurvy or its allied states of cachexy.

43. *H. The seasons* have no small influence on the appearance of scurvy, but mainly in consequence of the privation of fresh vegetables and fruits, which is experienced chiefly during winter and spring; so that, in armies, as well as in fleets in, or departing from, cold or temperate countries, a deficient supply of those dietetic means of prevention is more likely to be experienced at those seasons than at any other. Suppressed perspiration, produced by the cold and humidity of these seasons, may also not be altogether uninfluential, as shown above (§ 39.), in favouring the evolution of this malady. In northern countries, where the inhabitants, the seamen, and the soldiers, live chiefly upon cured meat provisions, as salted and smoked meats, and dried fish, during winter and spring, and until the commencement of summer, when vegetables and fruits begin to appear, their constitutions have made considerable progress to the scorbutic diathesis; so that, when these preventive articles of diet cannot be obtained at this latter season, owing either to states of siege, and to the provisioning and other circumstances of armies or fleets, scurvy is then much more apt to break out in spring, and even in summer, than at other seasons.

44. *I.* The earlier writers on scurvy were inclined to ascribe a *contagious influence* to this disease, chiefly from the number attacked with it in the same place and circumstances; but it was clearly shown that contagion had no share in producing it, by LIND and others, who wrote about the middle and end of the last century, the causes inducing the malady being common to all affected by it in the same locality. But although the disease is actually uncontagious, it is by no means unreasonable to infer, that the putrid emanations from a number of persons in an advanced stage of the disease, confined often in very limited spaces, either on board of ships, in the crowded hospitals of a besieged town, or in crowded prisons, are not altogether innocuous, or are not without some influence in predisposing the body to this or some allied malady, arising from the contamination of the circulating fluids, and from the depression of vital or organic nervous power, by the accumulation of these emanations in the air which is respired for a longer or shorter time. Nor would it be improbable that the emanations arising from a number of scorbutic patients, in places insufficiently ventilated, may convert the scorbutic malady into putrid, maculated, or putro-adynamic fever, or into scorbutic dysentery, or even may more directly develope these diseases.

45. *K. Age and sex* have probably but little influence on the production of scurvy, for it is observed at all ages, and in both sexes; but there is no doubt that it occurs much more frequently in adults, or from early puberty until far advanced age, than in children, and in males than in females, chiefly in consequence of the greater exposure of adult males to the causes, owing to the circumstances in which they are liable to be placed.

46. ii. THE EXCITING CAUSES OF SCURVY may be briefly stated to be the use, for a longer or shorter period, of all kinds of animal meats, too long or imperfectly cured or preserved; of dried, or smoked, or tainted meats or fish; or mouldy, old, damaged, diseased, or unripe farinaceous articles of food, to the exclusion of, or without possessing the advantages of, fresh or succulent vegetables and fruits, or of other preventive articles of diet, or of medicine; more especially when the use of the former kinds of food, and the want of the latter, are aided by one or more of the predisposing or concurring causes already considered. That the want or neglect of those vegetable productions which have been found so beneficial, both in preventing and in curing scurvy, has a greater influence in the production of the malady, than even the prolonged use of the several kinds of animal food, however cured or preserved, has been proved on various occasions. But it cannot be denied, that damaged, tainted, or too-long-cured substances, — pork, the viscera and blood of the animals generally used for food, — the flesh of animals which have died of disease, &c., are much more likely to occasion scurvy, and its various complications, than fresh and wholesome meats; although even these last may be followed by the disease, when too long or exclusively used, and when fresh vegetables and fruits cannot be obtained.

47. Although I cannot admit that scurvy is to be ascribed entirely and always to the absence or want of fresh succulent vegetables and fruits, as articles of diet, as contended for by Dr. BUDD, yet I will not deny that such a privation is the most common and exciting cause of the malady, espe-

cially when no suitable means are employed—none of the numerous preventives about to be noticed (§ 54. *et seq.*) is had recourse to, in order to supply the deficiency, or to counteract the effects resulting from the nature or state of the aliments. In this, as well as in other diseases, we cannot with propriety ascribe the sole agency to one cause; generally more than one, frequently several, although of diversified amount of power, are concerned in developing the result, whether that result be simple, definite, or specific, or whether it be complicated more or less, or contingently associated.

48. iii. *The chief causes insisted on by writers on this disease*, were often approaches only to the truth; but these approaches were sometimes so near, as to lead to judicious means of prevention and cure, although certain subordinate agencies were often overlooked. ECTHIUS, one of the earliest writers on scurvy, assigns as causes, "gross, unwholesome food of salt, dried, or semi-putrid flesh and fish, pork, spoiled bread, stinking water, &c." RONSSEUS ascribed the frequency of scurvy in Holland to the diet and air, to eating quantities of water-fowl, but chiefly to living on flesh first salted, then smoked and dried, and to the season and weather. WIERUS, who probably viewed cases of psoriasis as modifications of scurvy, and in this agreed with many who both preceded and followed him, more justly remarked the not infrequent connection of scurvy with ague and malignant forms of fever; and, with sufficient reason, ascribes this distemper "to unwholesome air, and chiefly to such bad or corrupt food as was used in northern countries, and by their shipping, viz., stinking pork, smoked rancid bacon, mouldy bread, thick, feculent ale, bad water, melancholy and grief of mind, preceding fevers, the stoppage of usual evacuations, &c." DODONÆUS imputed the scurvy in Brabant, in 1556, to the use of corrupted rye during a season of scarcity. ROSTOCK, in a treatise published in 1589, remarks, that impure water and bad air aid unwholesome food in producing scurvy, and states, that the disease is endemic in several northern countries, and that scorbutic mothers often there bear scorbutic children, and often miscarry, or bring forth dead fœtuses. BRUNNER insists upon the influence of damp, marshy localities, and other sources of malaria, in producing scurvy, and ascribes more to the nature of the bread used by the inhabitants of those localities than previous writers. HORSTIUS likewise insists upon the influence of malaria, and the use of new ale, without hops or any other bitter, in causing scurvy in various places in the North of Germany. VANDER MYE notices, more particularly than any previous writer, the influence of the emotions and passions of the mind in causing and in preventing scurvy, and adduces the effects of occurrences which took place during the siege of Breda, in support of his views. In this siege he attributed the disease chiefly to the general use of old, spoiled, or musty rye, and to humidity; but other causes, both physical and moral, were also in operation. He adds, that "the distemper proved most fatal to the English soldiers, as they very early began to feed on dog's flesh, were in want of their beloved tobacco, and lay in the most wet or damp barracks. It was much less frequent among the Walloons and Flemings, they being more careful and delicate in their diet, and having much wholesomer quarters. Amongst the French it was more rarely met with, owing to their being stationed in the driest part of the town, and to their more sprightly dispositions."

49. J. HARTMANN takes notice of the influence of mercury, and of mercurial courses, in predisposing to scurvy. In 1645, the medical faculty of Copenhagen published a consultation on the causes, prevention, and cure of the distemper, for the benefit of the poor of the country; and in this meritorious production, the influence of cold, humidity, malaria, and of unwholesome water and beverages, is insisted upon, as aiding the effects produced by food such as that already mentioned. MARTIN LISTER, and many of preceding and contemporary writers, and subsequently COCKBURN, PITCAIRN, BOERHAAVE, and others down to the appearance of BACHSTROM's work, in 1734, agree in ascribing scurvy to the use of unwholesome food and water, or to those causes chiefly which had been mentioned by their predecessors. But the last-named author was the first to demonstrate that, however much the food and water used were concerned in occasioning scurvy, *abstinence from recent vegetables was the chief cause of the malady, and the use of these the chief prevention and cure.* Notwithstanding this very decided opinion, and the very conclusive evidence BACHSTROM furnished of its truth, the disease has been imputed by writers, down almost to the present day, rather to the prolonged use of cured provisions, than to the want of fresh vegetables and fruit. But it is unnecessary to pursue this part of the subject any further.

50. Dr. LIND states that scurvy most commonly occurred on land in persons who subsisted chiefly on dried, or smoked, or salted flesh or fish, and the unfermented farines; or upon bread made of peas, or a composition of peas and oatmeal. KRAMER states that, in his time, this distemper appeared most frequently among those who lived altogether on boiled pulses, without any green vegetables or summer fruits. The occurrence of the disease among the Russian troops, whose chief food was rye-bread and meal, has been already noticed. Scurvy appeared among the inmates of a lunatic asylum in India, whose food consisted chiefly of rice and split peas; and Mr. MACOLMSON mentions the occurrence of the distemper in the same country among prisoners kept on bread and water. That various kinds of bread, especially when long kept, will occasion scurvy, or at least not prevent it, I believe, when they are not accompanied with succulent vegetables or fruits. But something is also owing to insufficiency, as well as sameness of diet, to living in a state of confinement, to breathing the air of the same place or habitation, and to the duration of this state of confinement: for it has always been remarked, that when this latter cause has been concerned in producing the disease, the first cases have been those longest confined. It may also be noticed, that the influence of farinaceous food in occasioning scurvy, is great in proportion to the length of time the articles have been kept previously, or subsequent to their usual modes of preparation, and to their healthy, or ripe, or untainted condition when predared. And it should be recollected, that flour, if sound and fresh, is more likely to prove beneficial when baked or otherwise prepared, shortly before it is used, than when it has been made into bread or biscuits a long time previously.

51. The prevalence of scurvy during 1847 and 1848, in Ireland, Scotland, and some parts of England, was very generally ascribed to the failure of the potato-crop. But in some places in Scotland, Dr. Christison imputed the disease to the privation of milk — an opion which has been negatived by numerous observations of the prevalence of scurvy where the supply of milk was abundant.

52. VI. The Nature of Scurvy may be inferred, with tolerable accuracy, especially as respects every practical purpose, from what has been adduced. But it is obvious, that the numerous occurrences of the distemper, both on land and at sea, as described at least by the majority of the writers referred to in the *Bibliography*, were associated with the appearance of one or more of those maladies, of which I have pointed out the relations with scurvy (§ 27. *et seq.*); and that, with many cases of scurvy, both simple and complicated, others of a different nature, as psoriasis, and various chronic eruptions, also appeared. To these circumstances, — to the extended signification thus imparted to the name, as well as to the complications it actually manifested, — are to be ascribed the diversity of description, and the numerous and complicated subdivisions of the malady, contained in works upon it during the 17th and 18th centuries. Opinions as to the nature or proximate cause of scurvy were no less diversified, and even numerous. Without attempting to adduce these opinions in full, or to connect them with their authors, it may be briefly remarked, that they generally agreed with the pathological doctrines of the day in which they respectively appeared, and were assigned by their authors, without any satisfactory proofs—were mere suppositions, or, at best, inferences from loosely-observed phenomena. Whilst some writers imputed scurvy to an acid state of the blood, others ascribed it to an alkaline condition of this fluid, and some even, to make more sure of the fact, considered that acidity in certain cases, and alkalinity in others, were its actual causes, the predominance of either condition giving rise to the different forms of the malady. These views not proving satisfactory, especially to those who had opinions of their own to propose, the existence of a predominant saline condition of the blood was supposed and accredited by many. But the particular salt was never shown, some considering it to be an acrid salt, others a rancid salt, and so on. Then came a viscid state of the blood to be asserted, then a vitiated as well as a viscid condition, and even the existence of a putrid ferment in the blood to be inferred. More recent writers considered that a simple dyscrasis of the blood only existed; others, not content with the simplicity of this view, thought it necessary to impart to it some special property or chemical quality, and contended that the dyscrasy was acid; and some were positive as to the dyscrasy being alkaline. Lastly, we find the distemper referred to the existence of a dyscrasis produced by the evolution of an acid ferment in the blood; the chief reason for the existence of this ferment being that an alkaline ferment could not exist; but the particular acid was not shown.

53. The chemical pathologists of the present day have not thrown much more light upon this part of the subject than their predecessors, each of whom considered his opinion as good as the former believed their own to have been. Dr. Christison supposes that scurvy arises from the want of vegetable albumen or animal casein in the food; and Dr. Garrod believes that the malady is caused by the absence of potash, and that potatoes, and other antiscorbutics owe their virtues to the potash they contain. Dr. Aldridge contends for the influence which should be ascribed to a deficiency of phosphorus, sulphur, lime, and the alkalies, in occasioning scurvy. That something may be owing—a part merely—to the causes contended for by Dr. Aldridge is not improbable. But it is unnecessary to pursue this subject any further than very briefly to state, that one of the most evident changes from the healthy condition is seated in the blood; but that this change is probably not the earliest in the procession of morbid phenómena, as it most certainly is not the only or the most advanced. That the change of the blood is, manifested by the sensible or physical properties, as well as by the chemical constitution of this fluid, will readily be admitted; and that, in consequence of this change, the several solids of the body are more or less affected, will also be conceded; but I contend that these are not the only alterations; for the vital qualities of the blood itself are more or less altered, or rather impaired, — those vital qualities which the blood derives from the organic nervous system, through the medium chiefly of the vessels in which it circulates. That the organic nervous system is early affected, either primarily, or through the medium of the blood, or in both modes, is shown, not merely by the functions, but also by the vital cohesion and organization, of the viscera and tissues which this system supplies and vitally actuates. But it is immaterial whether this system or the blood be the part primarily affected; for there can be no doubt that morbid states of the chyle, occasioned either by the nature and quality of the aliments, or by the defect of certain elements consequent upon the want of the requisite vegetable productions, or by both causes conjoined, will affect the assimilating functions, both by impairing organic nervous power, and by altering the constitution of the blood; the slow and gradual progress of these changes giving rise to all the structural, as well as functional alterations characterising the advanced stages of the malady.

54. VII. The Prevention of Scurvy.—*A.* The efficacy of *limes*, *lemons*, *shaddocks*, *oranges*, and *pomegranates*, in preventing scurvy, was known to several of the earlier writers on the disease, one of whom is quoted by Lind, in proof of the use thus made of these fruits by the Dutch seamen. Rousseus, Albertus, and other writers in the 16th century, make particular mention of lemons and oranges for the prevention and cure of scurvy. Although particular and convincing proofs of the efficacy of these were thus early furnished, not only by the Dutch, but also by some of our own early navigators, and subsequently by Admiral Wager, and others, insufficient attention was paid to the use of these fruits until the appearance of Dr. Lind's celebrated work on scurvy, at the middle of the last century. Notwithstanding the evidence so conclusively adduced by this able writer, these means of preventing scurvy were nevertheless more or less neglected, or were left to the caprice or choice of commanders and others, until the

efforts of BLANE, BLAIR, and TROTTER, towards the end of that century, succeeded in procuring the adoption of lime-juice for the naval service. The lemon and lime-juice now supplied to the navy, is preserved by the addition of one part of strong brandy to ten of the juice. But when the fruit can be procured, it is generally preferred, and is used, especially when it is actually required, with much pleasure and relish.

55. *B.* Other *fruits*, particularly those of an *acid nature*, and even the *sweet fruits* before they are ripe, are more or less efficacious in the prevention and cure of scurvy. Dr. TROTTER states that, having remarked that scorbutic slaves threw away ripe *guavas*, while they used the green fruit, he resolved to try the effects of such. He selected nine negroes, equally affected with scurvy. To three of those he gave limes, to three green guavas, and to three ripe guavas. They were served by himself; and at the end of a week, those who were restricted to the ripe fruit were nearly as before the experiment, while the others were almost well. M. FODÉRÉ states, that the good effects of *unripe grapes* were very apparent in the scorbutic cases of the French army of the Alps, in 1795. Sir J. PRINGLE recommended *apples* as a preventive in 1776; and Dr. TROTTER remarks that, "when Lord BRIDPORT's fleet arrived at Spithead, in September, 1795, almost every man in the fleet was more or less affected with scurvy. Large supplies of vegetables were provided; and lemon-juice being scarce, in consequence of the previous great consumption, fifty baskets of unripe apples were procured for the use of the fleet. The *Royal Sovereign*, in particular, derived great benefit from them;" and the cure of the disease was every where most speedy. *Tamarinds*, and most of the acidulous fruits of warm and hot climates, are more or less anti-scorbutic. When scurvy was prevalent among the troops at Rangoon, during the Burmese war of 1824, the *Phyllanthus emblica*, or anola, which has a rich, acid taste, was employed as an anti-scorbutic with much benefit.

56. When BACHSTROM asserted, in 1734, that scurvy was the result of a more or less protracted privation of fresh vegetables and fruits, he stated at the same time both its prevention and its cure; and although certain vegetables and fruits accomplished these purposes more quickly and fully than others, all those which are edible possess more or less of these beneficial properties. The writers of the 16th century have generally noticed the popular use of *scurvy-grass, brook-lime, water-cresses*, &c., for the prevention and cure of this distemper. All succulent vegetables and plants comprised in the order *Cruciferæ*, are more or less efficacious, especially the *radish, horse-radish, turnip, carrot, cabbage*, &c.; and even such of these as are commonly only used when boiled, are most efficacious when taken raw and fresh from the ground. Dr. LIND very justly insists upon this circumstance, and remarks that herbs in form of salads, are more efficacious than when boiled; and that their anti-scorbutic properties are destroyed by drying, as shown by KRAMER, and by the results observed from the anti-scorbutic herbs sent from Vienna to the army in Hungary. *Onions, garlic, leeks*, and *potatoes* are all very decidedly anti-scorbutic, and as these may be preserved for some time, they are most beneficial for the provisioning of ships or armies. The very general use of potatoes in modern times, partly accounts for the remarkably less prevalence of scurvy at the present day than formerly.

57. Most of the articles which are anti-scorbutic, may be preserved by *pickling*, especially by the pyroligneous acid or vinegar, and retain in a great degree their virtues. The immunity of Dutch vessels from scurvy has been ascribed by Dr. KERR and others to the use of *sour kroute;* and the health of the crew of the *Centurion*, during Captain COOK's voyage, was considered to have been owing to a liberal supply of this anti-scorbutic.* The quantity usually allowed of this substance was two pounds' weight to each man per week, besides a pound and a half, or two pounds, with every gallon of peas, for making soup.

58. There is no northern country where scurvy is generally endemic during winter, spring, and the early part of summer, that does not furnish a supply of anti-scorbutics, if duly recognised and preserved for these seasons. In Norway, Greenland, Iceland and Lapland they employ *scurvy-grass, sorrel*, and various other warm and acid herbs. Sir E. PARRY, in his first polar expedition, experienced the advantage of sorrel in the cases which occurred among his crews. He states that sorrel was preferred by the Esquimaux to scurvy-grass. He adopted also the advice of BACHSTROM and LIND, and raised small quantities of *mustard-and-cress* in his cabin, in small, shallow boxes, filled with mould, and placed along the stove-pipe; and as much of these were thus produced, although etiolated from want of light, as to prove beneficial to the scorbutic cases.

59. *C.* There is, perhaps, not any vegetable production more remarkably anti-scorbutic than the tribe of *firs*, especially the spruce-fir and common fir, and mountain-pine. MOELLENBROEK states, that when the Swedish army, at war with the Muscovites, were attacked with scurvy, Dr. ERBENIUS prescribed a *decoction of fir-tops*, by which the most deplorable cases were cured, and the rest of the troops protected from the distemper. Two squadrons of ships fitted out by Russia in 1736, were obliged to winter in Siberia, and their crews became affected with scurvy. After attempts to discover a remedy, the pines which grew plentifully on the adjoining mountains were hit upon; and by these all the men recovered in a few days (GMELIN, *Flor. Siber.*, p. 181.). Dr. LIND remarks, that pines and firs, as well as the shrub called the black spruce, have all analogous medicinal virtues, and great efficacy in the prevention and cure of this disease. "A simple decoction of the tops, cones, leaves, or even green bark and wood of these trees, is an excellent anti-scorbutic: but it becomes much more so when fermented, as in making spruce-beer, where the *molasses* contri-

---

* Dr. KERR, in his able treatise on scurvy, remarks, that "Sour kroute or croute (*sauer kraut*, Germ.) is prepared by slicing the soundest and most solid cabbages in the way cucumbers are used in this country. In this state they are put into a barrel in layers, hand high, and over each is strewed a handful of salt and carraway seeds: in this manner it is rammed down, stratum supra stratum, till the barrel is full, when a cover is put over it, and it is pressed down with a heavy weight. After standing for some time in this state, it begins to ferment; and it is not until the fermentation has entirely subsided, that the head is fitted to it, and the barrel is finally shut up and prepared for use."—*Cyclop. of Prac. Med.* vol. iii. p. 691.

butes, by its diaphoretic quality, to make it a more suitable medicine. By carrying a few bags of spruce to sea, this wholesome drink may be prepared at any time. But when it cannot be had, the common fir-tops should be first boiled in water, and the decoction afterwards fermented with molasses, in the common method of making spruce-beer, to which a small quantity of wormwood and horse-radish root (which it is easy to preserve fresh at sea) may be added."

60. *Tar-water* was formerly strongly recommended as an anti-scorbutic; but the extravagant praises bestowed upon it at the commencement of the last century, greatly injured its just reputation. Dr. LIND still continued to uphold it; and many years ago, I had occasion to have recourse to it as a preventive, when placed in circumstances most likely to occasion this distemper, and when no other means could be obtained.* There are many reasons to believe, that all the *terebinthinates* are anti-scorbutic; and that, when the disease is attended by hæmorrhage, there is no substance so efficacious as the spirit of turpentine, when taken in small and repeated doses, in arresting the hæmorrhage, in restoring the tone of the extreme vessels, and removing the contractions of the joints. With this impression, I recommended Sir E. PARRY to have a supply of this medicine in his last polar expedition; and he adopted the recommendation. The *anuda tree*, to which CARTIER attributed the remarkably quick recovery of his crew, is considered by LIND to have been the leaves and tops of the American spruce; and it, as well as the other pines and firs, evidently owed much of its virtues to the terebinthinate principles it contained.

61. *D. Molasses* have been considered by LIND and others as anti-scorbutic; and Sir G. BLANE states, that the ship in which it was first tried, was the only one in the squadron that was free from scurvy, which prevailed so much in the other ships, that, on their return to Portsmouth in August, 1780, 2400 men were sent to the hospital with this disease. Subsequently, molasses was served with rice to the men who were scorbutic, or threatened with scurvy, in Lord HOWE's fleet; and the benefit derived from it was so great, that it was made for some time a regular article in the victualling of ships. Nevertheless, the malady was not entirely prevented; and in some vessels well supplied with it, scurvy prevailed to a great extent. Dr. BUDD believes, that the anti-scorbutic properties of sugar-cane are greater than those of molasses; and that they are much impaired by the process employed in the manufacture of sugar. I consider this opinion to be correct, from what I have observed in warm climates.

62. An anonymous work on scurvy, published in 1767, recommended the use of *wort*, or an infusion of malt, as an anti-scorbutic; and this substance was afterwards favourably noticed by Dr. BADENOCH. Captain COOK employed it in the *Centurion*, and spoke highly of its efficacy. He took with him a large supply of malt, with which to make wort; of this from one to three pints were given daily to each man. Sir G. BLANE states, that the fleet in the West Indies was supplied with the *essence of malt*; that it proved of service, but that its anti-scorbutic properties were inconsiderable. The process of extracting the essence very probably impaired the properties possessed by the infusion.

63. *E. Various fermented liquors* have been used as anti-scorbutics, some of them from times immemorial, in northern countries. In Norway, in the Feroe and Shetland Isles, the inhabitants have, from the earliest ages, used, as their common beverages or drink, two kinds of fermented liquors; the one consisting of the fermented serum of butter-milk, or of fermented butter-milk, the caseous matter being removed as the fermentation proceeds; the other being an infusion of the bran or husks of oats and barley, that is fermented after the chief part of the farinaceous deposit from the infusion is removed. This deposit takes place from the infusion after this latter is poured off, or otherwise separated from the bran or husks. The infusion is then allowed to ferment, and the farinaceous deposit is removed, and used as an article of diet. These are very agreeable beverages, especially during the advanced stages of their fermentation, and constitute the common drink of the inhabitants. They are the chief means of averting scurvy in these parts, where fresh vegetables are either scarce, or not to be obtained, during a great part of the year, and where fruits are almost altogether wanting.

64. In all the continental countries bordering on the Baltic, and Northern and German oceans, *spruce-beer* is the most generally and most efficaciously used as a preventive of scurvy; vessels from Denmark, Sweden, Holland, Riga, Dantzic, &c., being generally provided either with it or with the essence of spruce, for their anti-scorbutic properties. Spruce-beer is beneficial, not only for the prevention and cure of scurvy, but also in the treatment of most fevers of a low type, and of several cachectic diseases; in all of which I have, since the commencement of my practice, frequently prescribed it. As shown above (§ 59.), it may be readily prepared from the materials which are easily procured, and as easily carried about. *Cyder* and *perry* are amongst the most decided anti-scorbutic beverages in use in this country, and were long ago shown to be very serviceable by Sir J. PRINGLE and Dr. LIND. *Small-beer*, in a state of brisk fermentation, is also anti-scorbutic, especially when a sufficient quantity of hops, or of a vegetable bitter, has been added. Sir G. BLANE and others have made a favourable mention of *malt-liquors*, and I have seen them used with advantage, especially *porter*, when bottled and well preserved.

65. The several kinds of *wine* are more or less

---

* The author of this work, in the winter of 1817 and 1818, was a passenger to England in a vessel, which was detained by bad weather at sea during thirteen weeks and four days, and which was provisioned and watered for seven or eight weeks only. He fortunately had laid in a small stock of articles for his own use; but, nevertheless, it was found necessary, after some time, to place every one on an abridged allowance of food and water. The meat provisions were altogether long salted, and were chiefly pork; the biscuit was coarse and mouldy. The water ultimately also was short in quantity, turbid, bluish, and most offensive. There fortunately was a very moderate supply of potatoes. During thirteen weeks no land had been seen, nor any other vessel communicated with. In this predicament — which, however, was not the only or the most dangerous one, — the author caused a small quantity of *tar* to be put into the water before it was used for drinking, and a little spirit was added. To these means, aided by a very moderate supply of potatoes, he attributed the preservation of the crew from scurvy and scorbutic dysentery, every person arriving in the Downs in good health notwithstanding the unwholesome supply of food and water, and the unfavourable season.

anti-scorbutic; and they are rendered still more so by the addition of vegetable bitters and aromatics, more particularly absinthium, calumba, cascarilla, ginger, orange and lemon-peel, &c. It has been observed that scurvy was rare in French ships of war in which the wines of their country were served out to the crews. Sir G. BLANE, Dr. LIND, and Dr. BRYSON agree in reprobating the use of spirituous liquors. There can be no doubt of the injurious tendency of these when taken in excess, or habitually, or undiluted. But used in small quantity, largely diluted, and added to the more common anti-scorbutic beverages, or to bitter vegetable infusions, they are decidedly beneficial, both in the prevention and cure of the distemper. There are various contingencies which occur to voyagers, requiring a cautious and moderate recourse to one or other of these liquors; and, in circumstances threatening the outbreak of scurvy, the addition of a small quantity of either of them to the means of prevention in common use, has a very beneficial influence upon the spirits and constitution of those who thus abstemiously use them, and promotes the good effects of the more efficacious anti-scorbutics, especially during exposures to cold and humidity.

66. *Vinegar* was early employed as an anti-scorbutic, and our fleets were generally supplied with it during the last century. Dr. LIND, Sir G. BLANE, Dr. TROTTER, and others, have shown that the distemper prevailed in ships which were well supplied with this article. Much, however, depends upon the kind of vinegar employed. The pyroligneous acetic acid certainly possesses considerable anti-scorbutic properties; much apparently depending upon the source and the preparation of this article. Dr. BUDD remarks, that he has observed scurvy in ships well supplied with vinegar; but the disease, in its most aggravated form, has appeared amongst those crews which had no regular allowance of this article.

67. *F.* The *mineral acids* have been found but little influential in the prevention and cure of scurvy. Dr. LIND took twelve patients on board of the *Salisbury*, at sea; their cases were quite similar. They lay in one place, and the diet was the same for all of them. Two of them were ordered a quart of *cyder* daily; two others took twenty-five drops of *elixir of vitriol* three times a day; two had two spoonfuls of *vinegar* thrice a day, and their food well acidulated with it; two were put on a course of *sea-water*, about half a pint having been given every day; two had each two *oranges* and one *lemon* daily; and two had the size of a nutmeg, three times a day, of an *electuary* made of *garlic*, *mustard-seed*, *rad. raphan.*, *balsam of Peru*, and *myrrh*; using barley-water, acidulated with *tamarinds*, for drink. The oranges and lemons were the most speedily beneficial; next to those the cyder: those who took the other medicines were, at the end of a fortnight, much in the same state as those who had taken only lenitive electuary and cream of tartar as an aperient.

68. *G.* There are numerous medicines besides those already mentioned, which are more or less useful in preventing as well as in curing scurvy. Most of the more *succulent* and *acidulous* vegetables, plants, and fruits, especially when fresh, or preserved by pyroligneous vinegar, are beneficial; but many of them lose their anti-scorbutic virtues when dried, and others when boiled. Of the medicines which may be used, and which are certainly occasionally serviceable, even when other means have failed, I may mention the *chlorate of potash*, *nitrate of potash*, *camphor*, the *chlorides*, *lime-water* and the *chloride of lime*, *chlorine*, *chlorinated water* and *chlorinated soda*, *sarsaparilla*, *serpentaria*, *sassafras*, *capsicum*, *taraxacum*, *guaiacum*, *mezereon*, *senega*, *elm-bark*, *dulcamara*, the several *balsams*, &c.; but these are severally only of use for certain modifications and complications of the malady.

69. It has been frequently supposed, and the supposition too often acted upon, that *fresh meat* is of itself sufficient to prevent or to cure scurvy when it breaks out in ships, and this opinion may supersede the opportunity of procuring fresh vegetables and fruits. Dr. BUDD states, that during the year in which he wrote on this disease, "the captain of a vessel trading to the Mauritius furnished his men, while they stayed at the island, with a plentiful supply of fresh beef, procured at considerable expense, but neglected to provide them with vegetables and limes which abound in the island. The consequence was, that scurvy broke out soon after they set sail, and before the ship arrived in this country one half the men before the mast had died of it, and the rest were disabled." (p. 77.)

70. *H.* It is not alone requisite to use the above means of prevention, as they may severally be possessed by individuals or communities, under circumstances which render the appearance of scurvy either probable or certain; but all the *predisposing and exciting causes* (§ 33. *et seq.*) *ought to be carefully avoided*, as far as this can be effected. I believe that no mean cause of the prevalence of scurvy in the navy, as well as in trading ships, was the habit, morning and evening, of washing the decks, thereby keeping in a constant state of humidity and evaporation, and the air either cold and humid, or close and humid, according to concomitant circumstances. This evil is partly abated by adopting dry scrubbing and similar means; but it still should be kept in recollection, as the adoption of it depends upon the knowledge or caprice of the captain, who in this, as well as in other matters connected with naval service, may, thus occasion an unhealthy state of air, an artificial malaria, the humidity favouring the concentration of emanation from the hold and other parts of the ship, and from the individuals confined during the night in a limited space and in a close air. Harassing duties, fatigue, and whatever lowers the general standard of health, or depresses the vital powers, ought also to be avoided.

71. *I.* Much, as will be seen from the above, depends upon the victualling of ships, especially those which proceed upon long voyages. The sailors should have a sufficient supply of cocoa, tea, coffee, fresh lemon-juice, sugar or molasses; and whilst spirituous liquors are allowed, in very moderate quantity, and only when wet or fatigued, they should either be withheld, or allowed in very small quantity only, when these exigencies do not exist. In circumstances tending to depress the mind, endeavours should be used to amuse and to excite it, in such ways as may the least tend to be followed by any depression. In these respects, as well as in others, the means adopted by Sir E. PARRY deserve both praise and adoption, as far as the latter is possible.

72. VIII. Treatment of Scurvy.—What has already been stated with reference to the *prevention* of scurvy, applies equally to the *treatment* of it, especially in its early stages, and less complicated or less severe states. But it is occasionally observed, that, owing either to the continued influence of certain causes which are overlooked, or cannot be removed, or to the presence of some complication, the disease resists the usual means of cure, and even those remedies which have generally been efficacious in the most severe cases. *Lime-juice*, and especially fresh *lemons* and *limes*, have been found the most efficacious means of cure in pure scurvy; but instances have been recorded very recently, in which lime-juice has failed. These instances of failure have, however, been adduced in too general terms, and without a sufficient and precise record of the several circumstances in which the failure occurred, or of the particulars in which the disease varied in its character from that usually observed. The distemper has commonly been stated to have been scurvy arising out of the usual causes; and lime-juice has been said to have been given without benefit; but no particulars are adduced as to the existence or non-existence of one or more of those predisposing and concurring causes described above (§ 33. *et seq.*), as not merely contributing to the production of the malady, but also actually perpetuating, modifying, or aggravating it, if they are allowed to continue in operation during the treatment. When lemons, limes, shaddocks, and oranges can be procured, they are preferable to other means; but, otherwise, the preserved lime-juice, or crystallised citric acid, should be substituted. In respect of the preserved juice, we have no adequate information as to the time it will retain its anti-scorbutic properties; for it is not unreasonable to infer, — indeed it has been proved — that, when this juice has been kept two or three years, as is not infrequently the case, it may have lost much of its virtues, the failure of it under such circumstances being sufficiently evident, without looking for the cause of failure in the nature of the disease itself, or in the inefficacy of the remedy.

73. One of our oldest English writers on scurvy, John Woodall, in his meritorious work entitled the "Surgeon's Mate,"—a name too vulgar to be noticed by doctors of modern manufacture,—observes that "we have many good things that heale the scurvy well on land, but the sea chirurgeon shall do little good at sea with them, neither will they endure. The use of the juyce of lemmons is a precious medicine, and well tried; being *sound and good*, let it have the chiefe place, for it well deserves it; the use whereof is: it is to be taken each morning, two or three spoonfulls, and fast after it two hours; and if you add one spoonful of *aqua vitæ* thereto, to a cold stomach, it is the better. Also, if you take a little thereof at night, it is good to mixe therewith sugar, or to take of the syrup thereof is not amisse." This good advice was given in 1636, and further insisted upon subsequently, by Martin Lister, Dellon, and many others; and yet when Lord Anson proceeded on his circumnavigation, no provision of the kind was made against scurvy; the prevention and cure of disease, and rewards for those who devote themselves to those laudable undertakings, never having been considered of any importance by British Governments, or, at least, of very minor importance only; the aggrandisement of party and family connections always absorbing and utterly annihilating considerations of public justice and patriotism.

74. Since the works of Lind, Trotter, and Blane established the reputation of lemon-juice, and acidulous fruits, for the cure of scurvy, these, with the use of fresh succulent vegetables, have been generally adopted. Nevertheless, other means have been resorted to, owing either to the failure of the lemon-juice, or to the form of, and circumstances attending, the malady. The other vegetable acids, and the mineral acids, have been found very remarkably inferior to the citric in the treatment of scurvy; but the amount of benefit which various kinds of salts, and the alkaline carbonates, are capable of affording, has not been ascertained, excepting in the single instance of nitre. Mr. Patterson, a naval surgeon, writing in 1794, showed the good effects of a solution of *nitrate of potash* in *vinegar*. He advised four ounces of nitre to be dissolved in a quart of vinegar, and gave half an ounce of this solution twice or thrice daily, and bathed the local sores with it as often. He states, that "some patients cannot bear the solution without the addition of water, whilst others, without the least inconvenience, bear it undiluted. The discharges by stool, or the presence of gripes or nausea, guide me with respect to increasing or diminishing the dose; but, at the same time, it is not a slight degree of nausea, colic, or diarrhœa that renders an alteration in the quantity of the medicine necessary. To a great number of scorbutic patients, eight ounces of this strong solution, containing one ounce of nitre, have, in the course of the day, as long as such a quantity was necessary, been administered to each with the greatest success. Also, large and frequently-repeated doses of this medicine have been given in cases of scorbutic dysentery, and instead of increasing, I have always found it remove the disease."

75. Mr. Cameron, another experienced naval surgeon, states, that having on several occasions observed the excellent effects of a solution of nitre, as recommended by Mr. Patterson, in scurvy, he was induced to employ it when the disease broke out among the prisoners on board of a convict-ship proceeding to Sydney in December, 1829, under his care. As soon as he commenced the use of this solution, many almost hopeless cases began to improve rapidly, and before one third of the voyage was accomplished, the health of the sick improved so fast under the new treatment, that he did not think it necessary to go into any port; and the general health of the prisoners (216.), when they arrived at Sydney, was much better than when they embarked in Ireland. Some of the cases manifested a severe pulmonary complication, but these also recovered. Mr. Cameron's preparation consisted of eight ounces of nitre, dissolved in sixty ounces of vinegar. Sometimes equal parts of vinegar and lime-juice were used: a little sugar was generally added, to render it more palatable, and a few drops of oil of peppermint, and a little alcohol. An ounce of this solution was a dose; and from three to eight doses, according to the stage and severity of the disease, were given at equal intervals, from six in the morning until eight at night.

76. It has been contended by Dr. Stephens, that the state of the blood in scurvy indicates the exhibition of the non-purgative salts, and not of acids. His own experience appears not to have furnished him with sufficient evidence in this matter. But I may mention, that in states of disease closely allied to scurvy, I have given, from an early period of my practice, the *chlorate of potash*, as well as the *carbonates of soda* and *potash*, with very marked benefit. In obstinate or complicated cases, or when the above means fail, a combination of these salts — of the nitrate and chlorate of potash, and the carbonate of soda or potash—may be tried; or the *chlorinated solutions of lime* or *of soda*. When diarrhœa is present, *lime-water* with milk, or small and frequent doses of the *chloride of lime*, or of *creasote*, in any demulcent vehicle, may be of use; and when hæmorrhages are present, small or moderate doses of the *terebinthinates*, or of the *spirits of turpentine*[*] (§§ 69, 60.), should be exhibited in any suitable form, or on the surface of spruce beer, when that beverage can be procured.

77. When the disease is *complicated* with *pleurisy*, or with *congestive pneumonia*, the nitre, with lime-juice and camphor, will be found beneficial; and epithems or embrocations applied to the chest or over the seat of pain, consisting of the compound camphor and turpentine liniments, will prove of essential service. When the disease is associated with disease of the *spleen*, as often occurs when it follows *intermittent* or *remittent fevers*, the preparations of cinchona or quinine, of serpentaria, guaiacum, &c., have frequently been found of service. In these, as well as in complications with *ague*, the remedies just mentioned should be exhibited in decided or sufficient doses; or various chalybeate preparations may be substituted, or given as circumstances may suggest. If the functions of the *liver* be torpid, or if congestions of this organ or of the spleen be indicated, the *nitro-hydrochloric acids* may be taken in weak solution, as the common drink, and the surface of the trunk, or the lower extremities sponged or bathed with the tepid or warm solution of these acids. In many circumstances of the disease, the compound decoction of *sarsaparilla*, or other preparations of this medicine, will be taken with advantage; and several of the substances mentioned above (§ 68. *et seq.*) will be beneficially conjoined with others, according as circumstances arise.

78. During the course of scurvy, whether simple or complicated, the *bowels* are often more or less disordered. When *costiveness* occurs, it should be removed by the less irritating but efficient means. The most appropriate, and the most successful, is a solution either of the *citrate of magnesia*, or of the *phosphate of soda*; or a sufficient quantity of *magnesia*, taken shortly before exhibiting the lemon-juice or the solution of citric acid. In order to keep the bowels sufficiently open, and to procure a return of the functions of the skin, magnesia may be taken conjoined with the precipitated *sulphur* and a little powdered ginger, in repeated doses. If *diarrhœa* or *dysentery* supervene, the means already mentioned, or those advised in another place (see Dysentery, Scorbutic), should be employed. If the evacuations be very offensive, as well as frequent, lime-water with milk, or the chloride of lime, or powdered charcoal, or tar-water, or creasote, will be found very beneficial; and to either of these, the calumus aromaticus, or other similar substances, may be added. M. Brachet states, that he has cured several cases of scurvy with powdered carbon alone.

79. As the disease approaches to, or assumes the characters of *putro-adynamic* or *maculated fever*, as observed sometimes under circumstances favouring this occurrence, the remedies advised above (§ 68.) for the complication of the distemper with ague; and various antiseptics, especially those recommended for the treatment of putro-adynamic or typhoid fevers (see Fevers, § 585. *et seq.*), should be prescribed with due decision, and appropriately to the features of individual cases. In all the states or complications of scurvy, as in low states of fever, approaching in character to those of scurvy, an *expectant practice* is not only a most dangerous, but a fatal one. The medical journals of the day — the middle of the 19th century — teem with the histories of cases of low fever, in which the practice was either expectant or inappropriate, as far as the treatment is recorded; the *post-mortem* changes revealing the results, which, by the experienced and observing physician, may have generally been anticipated.

80. The *diet* and *regimen* during the course of the malady, constitute the chief part of the treatment, and, as such, have been sufficiently noticed, in respect both of the prevention and cure of the malady. A warm, dry, and pure air (avoiding exposure to cold and wet) and moderate mental excitement, amusement, &c., will contribute very remarkably to the removal, as well as to prevention of scurvy.

[*] Very recently the spirits of turpentine has been recommended for hæmorrhages, as a new medicine for this class of diseases. I may mention, that, in a memoir, with experiments on the use of this remedy in disease, published by me in 1821, in the *London Medical and Physical Journal*, it was strongly advised to be prescribed for all hæmorrhagic affections; and the same advice has been given for these affections, as well as for numerous others, in this work.

SEROUS and SYNOVIAL MEMBRANES.

Synon. — *Membranes séreuses*, Fr.; — *Seröse Haüte, S. Ueberzüge, Wasser-haüte*, Germ.; — *Membranes Synoviales*, Fr.; — *Synovial-kapseln, Synovial-haüte*, Germ.

Classif. — See *art.* Peritoneum, Pleura, &c.

1. The *pathology* and *diseases* of *Serous* and *Synovial membranes* have been so fully considered in the *articles* Peritoneum, Pleura, Brain, Membranes of, that a description of the *organic changes* presented by these membranes would be only a repetition of what has been already stated under these heads. As respects these changes, whether those consequent upon the several states of inflammation, or those arising from constitutional causes, or vice, and altogether independent of inflammation, I believe that they will be found to be more fully described, at the places now referred to, than anywhere else. Since these articles were written, the very excellent works of Rokitansky, and the able treatise of Dr. Brinton on the pathology of serous and synovial membranes have appeared; but after attentively perusing these, I find nothing that requires to be added, at this place, by way of appendix to the articles just enumerated. Indeed, there is one lesion, or rather ultimate change, consequent, in rare instances, upon *chronic peritonitis* and *chronic pleuritis*, lately seen by me in these maladies, which is not noticed by either of these writers, namely, the complete degeneration of the greater part of he organised exudation, false membranes, or adhesions produced by these diseases, as well as by chronic inflammation of the serous membrane of the spinal marrow, into fat. This ultimate change, observed by me in these three situations, in old, or very chronic cases of these maladies, appeared to be not merely a far-advanced change, but also a reparative one, admitting of a partial return of the functions of the parts adjoining (see *art.* Pleura, § 100.).

2. The contractions also produced in cases of chronic inflammation of the peritoneum, described by Dr. Hodgkin and myself, have also not been mentioned by these writers. (See *art.* Peritoneum, § 116.)

3. It is almost unnecessary to state, that the organic changes met with in the membranes usually denominated *serous*, occur also in those commonly termed *synovial*, their intimate structures being alike, although their connections are different.

SHOCK, VITAL or NERVOUS.

Synon. — *Sudden sinking of Vitality*; — *Vital Depression*; — *Nervous Shock*, — *Nervous Depression*, — *Fatal Sinking, &c.*

Classif. — I. Class. I. Order (*Author*).

Definit. — *Sudden or instantaneous depression of organic nervous, or vital power, often with more or less perturbation of body and mind, passing either into reaction, or into fatal sinking, occasioned by the nature, severity, or extent of injury, or by an overwhelming moral calamity.*

1. A *shock*, whether physical or moral, may present any grade of severity, from merely a slight but sudden depression of the vital functions, to the rapid extinction of these functions. From its slighter forms, the powers of life react sooner or later, especially when judiciously aided; but its more intense states are either removed with great difficulty, or they proceed, with various rates of celerity, to a fatal issue; the vital sinking increasing more or less rapidly, and extending from the organs more strictly vital to all other parts, — from the seat of injury to the solar ganglion, and thence to the heart, respiratory apparatus, brain, spinal chord, muscles, and senses, — until the functions of all are extinguished. *Vital shock* varies, not only in severity and fatal tendency, but also somewhat in its phenomena, according to the constitution and vital energies of the sufferer, and the nature of the cause.

2. Although the effects of shock have been recognised by most observing persons, even by the uneducated, yet they have received extremely little attention from medical men; they have not been noticed, either in medical or in surgical writings, excepting very casually in some surgical works; and I believe that they are now treated of for the first time in a systematic medical work.* It is necessary to distinguish *shock* from *concussion*; for although concussion, whether of the head or of the spine, is generally attended with more or less of vital shock, still concussion concerns chiefly the functions of either the brain, or spinal chord, or of both, according as the injury is directed to either or both of these quarters. The severity and danger of shock depends, not upon the amount of pain produced, but rather upon the suddenness and violence of the injury, relatively to the amount of vital resistance; for when a cannon-ball, or any other ball, carries off a limb, or does other fatal injury, pain is not produced, but the vital shock is extreme, the general depression,

---

* The diseases of the Cæcum and its *Appendix* were fully described, and their treatment pointed out in this work, long before they received any adequate attention elsewhere. Some years afterwards papers were published on that subject in the Transactions of the Medical and Chirurgical Society; and the learned author of these papers commenced with the veracious statement, that the subject had never engaged the attention of any previous writer, although the comprehensive article on the subject in this work is sufficiently extensive to make a small volume, and it was then in the hands of many thousand readers. It is to be hoped, that the present article may receive attention, but not quite similar attention, especially from Surgical readers, whom it more especially interests. "*Sic vos non vobis*," &c.

or vital sinking, often passing rapidly to dissolution.

3. Pain of itself rarely occasions, although it may accompany shock, and, when it does, it generally tends to diminish shock, and to develope reaction. Pain and shock are often associated in injuries and surgical operations; but the former is an endowment tending to the protection of life, to the counteraction of the effects of shock, and to the development of a salutary vital reaction. The severest or most prolonged pain does not occasion vital shock, but it causes vital exhaustion, sometimes even sleep. This was proved by the tortures of the rack in former times, and by the history of the most painful affections. When pain attends severe injuries and operations, the patient sinking more or less speedily, the result should be imputed to the influence of the shock on the constitution, and not to the pain, which is merely unavailing in counteracting the fatal result. This view of the subject, I am aware, is very different from what is generally taken; but a more intimate consideration of the phenomena, than has hitherto been entertained, will show its truth. The importance of this topic is remarkably heightened at the present day by the circumstance of anæsthetics being so generally employed during operations, and even during parturition; for if the view I now take be just, the shock to the constitution, or vital influence, by severe operations, or by a severe labour, will be increased by annihilating the preservative influence of pain; and the immediate, as well as the more remote effects of shock will be thereby more or less increased.

4. In the article, Poisons, I have shown the effects produced by the *inhalation of chloroform and æther* (§§ 615, 616.). It may be useful to view these effects in connection with those produced by dangerous or fatal injuries, and to contrast them as far as they admit of contrast. It will be seen, by observing the progressive effects of chloroform, that it paralyses sensibility, and subsequently, as its influence extends to the medulla oblongata, it more or less paralyses the respiratory functions, and ultimately the heart itself, if its inhalation be continued sufficiently long to produce this effect; the functions of the brain, of the medula oblongata, and of the ganglial system, being successively extinguished. The effects of fatal shock are similar as respects the sinking and extinction of the functions of these several organs, but they present a different order of procession, as will be more fully shown hereafter, the ganglial and cerebro-spinal functions being successively affected. Now, as the effects produced by the inhalation of chloroform are depressing as well as anæsthetic, and as shock is also depressing, although in a somewhat different manner, must it not be reasonable to infer, that the shock will be more severe and dangerous, cæteris paribus, during the influence or effects of chloroform, than when the frame is unaffected by this agent, and when pain exerts its influence, and developes a salutary vital resistance? In this matter, the ascertainment of truth is my object. I reason from my own observation, as far as it has extended, and I leave this part of my subject to those who have had, or may have, a more extensive experience of the phenomena to which these remarks apply.

5. Shock produces effects of various grades of severity, according to the health, or the states of depression or of excitement, the individual may be in at the time of sustaining it. Thus a person of a powerful constitution is much less affected by it than a delicate, nervous, or melancholic individual. A state of excitement, anger, passion, &c., to a certain extent, counteracts its effects, whilst fear, grief, or any of the depressing passions, increase its effects. Even pre-existing disorder, or structural change, renders these effects more dangerous or severe, especially organic change of the structure, or of the cavities or valves, of the heart. These are important circumstances as respects persons for whom severe operations may be required, and should be kept in recollection when such operations are about to be determined on. Whilst the *severity* of shock is thus influenced by constitution, temperament, states of mind, and existing disorder or actual organic disease, the *phenomena* constituting shock are also modified, by these circumstances, in a more or less remarkable manner. The intensity, as well as the modifications of the phenomena of shock, is very remarkably influenced, or even in great measure occasioned, by the state or amount of alarm produced in the mind of the sufferer by the injury causing the shock; this is the more remarkable in severe wounds and other injuries.

6. From these considerations, it will be readily inferred, that the *symptoms* or *phenomena of shock* will vary more or less in different cases, according as one or several of these modifying causes are in operation; and that, whilst certain of them may be wanting in some instances, the whole may be differently grouped, or may appear in varied succession, in most cases.

7. I. Phenomena of Shock. — The *symptoms* of shock vary with the severity or intensity, and nature of the *cause*, and the state or constitution of the recipient. — The *causes* of shock are chiefly, 1st, contusions, bruises, blows, and concussions; and these vary in their effects, according to their situation upon or near vital or important organs, as when they are seated over or near the epigastrium, the cranium or neck, the joints, the spine, &c. 2d. Gun-shot wounds, by which large nerves, blood-vessels, or important viscera, or joints, or large bones, are more or less injured. 3d. Penetrating or incised wounds, or surgical operations, implicating these or other parts. 4th. Simple or compound fractures, dislocations, lacerations, or lacerated injuries of all kinds; and 5th. Mental alarm or terror, or shocks from the sudden or unexpected intelligence of losses of near relations, of friends, of wealth, of honour, or of worldly consideration, or intense fear or dread of some calamity. In many of the preceding classes of causes of shock, mental alarm or dread — the mental shock — greatly increases the effects of the physical shock upon the vitality of the frame, and especially on the manifestations of life in the nervous system; so that in estimating the amount of the latter, care should be taken not to overlook the existence and intensity of the former — of the mental alarm or shock.

8. Now, although these several classes of injury, with their frequent attendant, mental alarm or shock, may be supposed to produce varied effects, yet such is not always the case; for so much may be owing to the severity, as well as the nature of the cause, relatively to the state and constitu-

tion of the sufferer, that the phenomena consequent upon the one class may hardly vary from those following the others. So much, however, is often observed to depend upon the viscera and parts injured, and upon the loss of blood, and the amount of that loss, as well as upon the intensity of mental alarm, as to render it necessary to connect the shock, and its intensity, with the nature and severity of the cause, or causes, which produced it. For, according to the cause, (1st) the shock may be altogether and simply a vital one, as when it is produced by a violent blow on the epigastrium, occasioning concussion of the solar ganglion; (2nd) or it may be associated with various nervous phenomena, as when a large nerve, or joint, or limb, is lacerated or severely injured, and the patient thereby greatly alarmed; (3rd) or it may be complicated with, or rather characterised by, comatose sinking, as when the contusion, concussion, or blow, affects the intimate organization and circulation of the brain; (4th) or it may be so associated with the sinking consequent upon losses of blood, as not to be distinguished from this cause, especially when the injury is such as occasions both shock and hæmorrhage; or (5th) the alarm or shock may be entirely a mental one, or that consisting entirely of the sudden effects of extremely depressing emotions on the action of the heart, or of the sudden and unexpected intelligence of distressing losses or events, whereby the nervous system is more or less shocked, the mental manifestations disturbed, and the functions of the heart and vital organs depressed and otherwise disordered.

9. It will thus be perceived, that the injuries or *causes* occasioning shock may be divided into *five classes*, and that the effects they produce may present *five modified forms*; but although either of these may result from either class of causes, and although it is necessary to connect, our observation of the phenomena, and our treatment of shock, with the particular cause of it, it is still more important, especially as regards the treatment, to mark the particular form and modification requiring our aid.

10. (*a.*) The *simple* or more *vital states* of shock may be so slight as to pass off in a few hours, or so severe as to terminate fatally in a few minutes, according to the intensity of the cause. This effect may be altogether independent of any hæmorrhage, and may result from a variety of causes. A violent blow or contusion over or near the epigastric centre, may so paralyze the heart, as to produce more or less sinking, not only of the action of this organ, but of all the vital functions; the *symptoms* being chiefly feebleness, slowness, or irregularity of the pulse; coldness and pallor of the face, general surface, and extremities; a distressing feeling of sinking and anxiety; slow or irregular respiration; sometimes cold perspiration, with general tremor; and a sunken or collapsed state of the countenance, terminating, more or less rapidly, in loss of pulse at the extremities and in the carotids, and in extinction of sensation, of the heart's action, and of respiration. In some cases, especially when the injury is less intense, or when a large joint is very severely injured, or crushed, these symptoms may not be so intense, may be of longer duration, and be attended by others, as vomiting, singultus, or by restlessness, by feelings of alarm and anxiety at the epigastrium; and, according to the nature and severity of the cause, relatively to the state of the sufferer, these symptoms may lapse into fatal sinking, or be followed by imperfect efforts at reaction, or by delirium, or by reaction, terminating ultimately either in coma and death or in recovery, according to the constitution of the patient, and the treatment adopted.

11. (*b.*) With more or less of the above symptoms, others may supervene, or may be present from the first, more especially when a limb is carried away by a cannon-ball, or when it is lacerated extensively, or near to the trunk of the body, or when large blood-vessels or nerves are lacerated, or large joints are crushed. In these circumstances, as well as in others, especially in nervous and irritable temperaments, various *nervous symptoms*, especially mental alarm and restlessness; irregularity of the heart's action and of respiration; a terrified, as well as a sunk state of the countenance; delirium, terror, and incoherence; a general tremor and coldness; a remarkable and peculiar tremor or quivering of the injured limb, with a cold, wet, pallid, or leaden state of the surface of the limb, or parts adjoining, are more or less remarkable, and seldom terminate in a salutary reaction, unless in a few cases, which admit of surgical interference by amputation, &c. When severe injuries are inflicted upon any part of the abdominal cavity, a state of stupor or apathy, yellowness of the surface of the body, collapsed features, and fatal sinking, as already described (§ 10.), either appear from the first, or supervene upon the symptoms just enumerated. In most of these severe injuries, and especially those produced by fire-arms, the amount of pain is very small compared with the intensity of the shock; and even where the shock is the greatest, the pain may be the least, or may even be entirely absent. Indeed, in many cases, the pain precedes the occurrence of reaction, and even favours the development of this salutary effort of nature.

12. Although surgeons have neglected to treat specifically of *shock*, — a state which particularly concerns them, as respects both the period and the prudence of operating, and the effects of operations, — the subject has been briefly adverted to by many, and especially by Larrey, Guthrie, Copland Hutchison, Dupuytren, and Hennen. It falls not within the scope of this work, to notice the remarks they have offered respecting it; but what they have advanced — which is extremely little — will be readily found in the works of these celebrated surgeons.

13. (*c.*) Injuries may be received directly or indirectly by the brain or spinal marrow, so as to produce a form of shock, which has been generally termed *concussion of the brain*, or of the *spinal chord*, as either may be affected. In such cases, with more or less shock to vitality, or to the frame, there is a special shock sustained by these nervous centres, the minute or ultimate organization and circulation of these parts being so changed or affected, as to instantly arrest all the functions they perform. With the phenomena of shock, as manifested in its more simple form (§ 10.), unconscious fæcal and urinary evacuations, sometimes with vomitings, are also present. When the injury thus implicates the brain, or upper portion of the spinal chord, the annihilation of the functions of

those parts especially distinguishes the case, although the marked and often rapid sinking of the heart's action, or the paralysis of the respiratory muscles, further characterises it, either of these being the more immediate cause of dissolution.

14. (*d.*) Cases often occur in which the shock is heightened by, or complicated with, either *internal*, or *concealed*, or *open hæmorrhage.* In these, the symptoms of simple shock (§ 10.) are more or less manifest, with great pallor of the surface, often with coldness and tremor, sometimes with succussions, or shudderings, or vomitings, passing into deliquium, or fatal sinking, especially when attempting to sit up. The action of the heart then ceases, and with it respiration; the cerebral functions either being but slightly disturbed, unless shortly before death, or ceasing in a way not to be distinguished from the accession of sleep, excepting in the rapid failure of the pulse and respiration. In the less severe cases of this kind, reaction may supervene, and recovery take place, when the nature of the injury causing the shock and hæmorrhage, and the consequences of both, admit of this issue.

15. (*e.*) The *fifth form* of shock depends more or less on mental causes of an intensely depressing nature. The physical effect may be entirely owing to the mental cause, or partly owing to this cause, or to alarm or dread of dissolution in connection with a physical cause, as in cases of gun-shot or other wounds, severe injuries, operations, &c. In these latter cases, the causes are both physical and mental; and the phenomena present a mixed character, more or less of mental alarm or of nervous phenomena, such as are above noticed (§ 11.) being associated with physical depression,— the symptoms of either the *first* or the *second* of these forms predominating with fright, anxiety, or most manifest alarm and distress, or of absolute terror, or even delirium, sometimes, in females, with hysterical convulsions, prolonged faintness or catalepsy. In this form of shock, the strength of mind, the nervous energy, or force of character of the sufferer, modifies remarkably the amount or intensity, as well as the particular form or state, of the physical effect; for the same intensity of cause, which might make but slight impression on a person thus mentally constituted, or on one physically robust, might produce a very dangerous effect on a delicate, nervous, and susceptible individual; this effect being, moreover, often attended by faintness, convulsions, incoherence, &c. Mental shock is more especially depressing and dangerous to persons who are the subject of organic diseases of the heart, or brain — of the former particularly — death often immediately following it.

16. II. The DIAGNOSIS and PROGNOSIS OF SHOCK require but little remark. — *A.* Of the *former*, it may be observed, that it is often difficult to determine whether or no a fatal result be owing to the immediate physical shock and mental alarm which an injury or operation produces, or to the consecutive effects on the frame, either by interrupting some important or vital function, or by contaminating the blood. True or simple shock is always instantly manifested on the cause producing it; it is generally attended by nearly all the symptoms already enumerated, by more or less mental alarm, and by a sensation of sinking and anxiety referred to the epigastrium and præcordia, sometimes with vomitings, characterised by slight, or even no effort, or with unconscious or involuntary evacuations, and an universal failure of all the vital functions. In some of the most severe cases of physical shock, instead of mental alarm, there is either delirium, or stupor, or apathy.

17. *B.* The *Prognosis* depends entirely upon the nature of the cause or injury, and the intensity of the effect indicated by the symptoms. Great slowness, or weakness of the pulse; or great frequency with feebleness, or irregularity; marked coldness, pallor or leaden hue of the surface; tremor, cold perspirations, vomitings, singultus; irregularity of the respiration; continual restlessness; a sensation of sinking or of impending dissolution; delirium, apathy, or stupor; involuntary evacuations; a jaundiced appearance of the surface; rapid failure of the pulse, &c., are all very dangerous, and often fatal symptoms. When the phenomena are less severe, and when the means employed are successful in bringing about a salutary reaction, or even in diminishing the severity of those now mentioned, then hopes of recovery may be entertained. But so much depends upon the nature and peculiarities of the case, upon the patient's feelings and opinions as to the issue, which should always be duly considered, and upon the progress and contingencies of the after-treatment, especially for complicated injuries, as hardly to admit of definite laws of prognosis being assigned.

18. Many of the injuries which occasion severe shock, involve the questions, 1st, as to the propriety of amputating a limb, or shattered or torn stump; and, 2nd, as to the period at which this operation should be performed. The first of these questions has been satisfactorily considered by surgical writers; but the second has been long a subject of discussion, many writers of experience taking different views of the matter. The differences of opinion, as well as of success, as regards the period, after these injuries, at which the operation should be performed, have arisen from the want of due attention to the existence or non-existence of the more marked phenomena of shock at the time of performing the operation, and from recourse having been too frequently had to it before these phenomena had subsided, or before the frame had recovered itself, either partially or more fully, from the shock it had experienced — before vital reaction had commenced; for, if a few hours be not allowed for this purpose, before the operation be attempted, the performance of it so rapidly upon the receipt of the injury may convert a state of shock, admitting of vital reaction, into a state of fatal sinking; or, if the vital energies continue to sink more and more, during the few hours thus allowed for them to rally, notwithstanding a recourse to rational means to this end, an operation will only add to the patient's suffering and accelerate the fatal issue.

19. III. TREATMENT OF SHOCK. — *The treatment of the more simple states* of physical shock (§ 10.) should be appropriate to the intensity or apparent danger of the symptoms. In the *slighter forms*, warm diluents, the application of external warmth, the allaying of mental alarm, a cheerful confidence evinced by the attendants, and a moderate recourse to gentle stimuli or restoratives, such as camphor, ammonia, æther, &c., in small doses, are generally all that may be re-

quired. But, in *severer* or *dangerous cases*, a more assiduous and a more liberal recourse to these means is absolutely necessary, and should be continued until indications of commencing reaction appear. In these, as well as in others of more imminent danger, even an assiduous and a decided use of these means may be insufficient to bring about the desired effect; and others must be brought to their aid. In these cases, more especially, the existence of mental alarm should be taken into account, and where it is inferred, — for it may exist without being made apparent, — the patient should be assured and encouraged. In all cases of a severe and dangerous nature, and where the occasion admits of having recourse to the means, the patient should be placed in a bed previously well warmed, and two young persons, according to the sex which may be proper, ought to be placed close to him, one on each side, without any intervening covering; and warmth should be promoted by sufficient bed-clothes. In some countries, it has been customary to apply animal heat in a different way, namely, by the skins of animals, torn from their bodies instantly on their being killed, and the internal surfaces applied directly to the patient's body, or even the opened bodies of the animals themselves, whilst still warm. I have seen these means employed, and certainly with greater success than I expected. In cases of shock from blows or contusions on the abdomen, or near the epigastrium, these means are appropriate, and their success admits of rational explanation.

20. In some cases, a stimulating or medicated warm-bath may be tried, salt, mustard, &c., having been added to the water. I do not, however, consider these as efficacious as animal warmth applied in either of the ways just mentioned; and I have generally preferred to warm baths, as being more efficacious, more immediate, and attended with less trouble and fatigue, or exertion, on the part of the patient, the application of flannels, wrung as dry as possible out of very warm water, then freely sprinkled with spirits of turpentine, and instantly applied over the epigastrium and whole abdomen, evaporation from them being prevented by dry cloths or oil-skin placed over them. These hot epithems should be continued or renewed until reaction commences, when they, as well as the internal means had recourse to, ought to be discontinued, and the case subsequently treated according to its peculiar requirements.

21. In those cases which present, from the nature of the injury, more or less of the nervous symptoms above noticed (§ 11.), various nervine remedies, in addition to those already mentioned, may be employed. In these more especially, and sometimes in others, opium, in certain states of combination particularly, is often of service. In conjunction with camphor, or with ether, or with ammonia and aromatics, it is a most valuable remedy. When delirium is present, camphor is required in full doses; whilst the addition of opium, or of morphia, soothes the irritability, and allays the restlessness sometimes present, and diminishes the mental alarm. But when delirium occurs, its passage into coma should be dreaded, and opium and other narcotics should be used with caution, and only in combination with camphor and other restoratives and anti-spasmodics.

22. When the hæmorrhage caused by injuries is so great as to increase the vital sinking attendant on shock, and especially when it increases the alarm of the patient, means appropriate to the circumstances of the case should be taken to arrest it. Prolonged faintness, coldness of the surface, and slowness or irregularity of the pulse, require a decided use of the means already mentioned (§ 19. *et seq.*), aided by the exhibition of ammonia, wine, warm, strong coffee, the horizontal position, and the external application of warmth, as already advised (§ 20.). If vomitings accompany this or other states of shock, the hot epithems prescribed above should be assiduously employed; and especially if convulsions or spasms of any part be complained of. Effervescing draughts, with the ammonia in excess, with opium, camphor, ether, &c., may also be given, or pills containing creasote, opium, and aromatics.

23. The terror and mental alarm often increasing the physical shock in most cases of severe injury, should be combated by the confidence and encouragement of the medical attendants, by a recourse to opium, ammonia, ether, mulled wine, &c. The states of mental shock produced by sudden and alarming moral causes, may occasion so severe physical effects, as to require similar means to those already advised. Faintness, more or less prolonged or repeated, or hysterical convulsions, or spasms, or delirium, may complicate the physical depression, and require the exhibition of diffusive stimulants, conjoined with anti-spasmodics and anodynes. In cases of general shock, from concussion of the brain or spine, the internal use of stimuli may not be required, and it should at all times be administered with caution. The turpentine epithem (§ 20.) may, however, be applied along the spine, when it is the special seat of shock, or even around the cranium, when the concussion implicates the brain, and an enema may be administered containing assafœtida, with a moderate quantity of camphor. But a recourse to these, or other means, should depend much upon the states of the pulse, and of the sensorium, at the time.

24. The external or local means must be left to the judgment of the medical attendant. Cold applications ought not to be made to the seat of injury, as long as coldness of the surface, collapse of the features, and failure of the pulse exist. They will not only aggravate these symptoms, but also increase the anxiety, sinking, and pain at the epigastrium, and the general restlessness and distress. Warm fomentations, with a decoction of poppy-heads, especially if much pain be experienced, or warm embrocations containing some preparation of opium, will generally afford some relief.

25. The injury, especially those produced by gun-shots, severe compound fractures, lacerations, &c., may require the removal of the limb. In this case, if the phenomena of shock produced by the injury be severe, this operation should not be performed until the constitution shows indications of rallying, either by the efforts of nature, — owing to the vital resistance in less severe cases, — or by the means above recommended. A few hours should be allowed for this purpose, — often not more than two or three, — seldom more than eight or ten hours; for if, at the termination of this longer time, reaction has not commenced, and

more especially if the vital depression has increased, the additional shock produced by the operation may rapidly terminate life. It will be better, therefore, to persevere somewhat longer in the use of the means advised for rallying the powers of life, and to increase the doses of these means, always with due reference to the previous habits of the patient, than to attempt an operation which will be of no avail.

26. As soon as indications of *vital restoration*, or of *vascular reaction* appear, the means resorted to for attaining this end should be relinquished; and gentle diaphoretics be given with the view of equalising the circulation and removing internal congestions, which are apt to occur during the vital depression caused by the shock. If the reaction be such as is attedned by heat and dryness of skin, full or strong pulse, thirst, &c., cooling diaphoretics, purgatives, and even blood-letting, especially if the previous loss of blood has been inconsiderable, should be prescribed; and these should be aided by such local means, in cases of severe injury, as their nature may require.

27. The reaction following mental shocks, especially in nervous, susceptible, and delicate persons, and females, is apt to be followed by *delirium* or *fever*, sometimes by *phrenitis* and inflammation of the brain or its membranes, on either of which *coma* is liable to supervene, and similar consequences may follow concussions of the brain or spinal marrow; in such circumstances, the treatment recommended for these diseases, under their respective heads, should be adopted. (*See arts.* BRAIN and its MEMBRANES, INFLAMMATIONS of; also DELIRIUM, COMA, &c.)

28. In some instances, instead of either a salutary reaction or increased or inflammatory action of the nervous centres, or their membranes, the shock, whether mental or physical, degenerates into a low, incoherent, or muttering *delirium*, passing more or less rapidly into *coma* (§ 27.). In these circumstances, recovery rarely takes place; but, nevertheless, a strenuous recourse to the restorative means already mentioned, such as frequent doses of camphor, or ammonia, terebinthinate epithems on the scalp and epigastrium, stimulating enemata, &c., should not be neglected. (*See arts.* DELIRIUM and COMA.)

BIBLIOG. AND REFER.—I am not acquainted with any work or treatise on vital or nervous Shock, and but few writers notice it incidentally, far less describe it, or advise a treatment suitable to its several states. I have treated of Shock in this work, because I consider it a most important and dangerous affection implicating more or less the whole vital and animal functions, and hence, coming strictly within the province of the physician, as well as within that of the surgeon. When we consider that, of the numerous accidents and wounds which cause death, the greater proportion produce this effect by the severity and suddenness of the shock to the vitality of the frame, rather than by any interruption to the functions of the injured part, the interest of this subject will appear in its true light. The principal works in which it is incidentally mentioned are the following: — *Larrey*, Mém. de Chirurg. Militaire. 4 tomes, 8vo. Paris, 1812—17. — *G. Guthrie*, On Gun-shot Wounds of the Extremities, 3d ed. 8vo. Lond. 1827; and on Wounds and Injuries of the Abdomen and Pelvis, 8vo. Lond. 1847. — *J. Hennen*, Principles of Military Surgery, 2d ed. Edin. 8vo. 1820. — *A. Copland Hutchison*, Practical Observations in Surgery, 8vo. 2d ed. 1826; and Observations on the Period for Amputating in Gun-shot Wounds, 8vo. Lond. 1817. — *Dupuytren*, Leçons Orales de Chirug. Clin. t. ii. art. 7. t. iv. art. 7. et 14. — *S. Cooper*, Surgical Dictionary, 7th ed. 8vo. Lond. 1838, p. 650.

SKIN:—SYNON.—*Integuments; Integumental Sac, or envelope of the frame; Cutis, Corium, Derma;* — *die Haut, das Fell,* Germ.; — *Peau,* Fr.

CLASSIF. — GENERAL and SPECIAL PATHOLOGY — SYMPTOMATOLOGY.

1. I. FUNCTIONAL ALTERATIONS. — The *skin*, or integumental sac or covering of the body, discharges more important functions than have commonly been imputed to it. I long ago, and more recently in various parts of this work, endeavoured to prove, that the skin performs offices of a very high order in the œconomy; that through it, effete and excrementitious matters are carried out of the blood, and that in this respect, as a depurating organ, it aids the functions of the kidneys, of the large bowels, and of the lungs; an impairment of the functions of either of these being often attended by a vicarious increase of its actions. It is thus an eliminating organ, contributing to the depuration of the blood, generally to an extent more or less intimately related to the amount of function performed by the other emunctories. That the skin performs a vital action, consisting of an insensible and a sensible exhalation the amount of either depending much upon the state of the atmosphere, is generally admitted. Increased transpiration may proceed from a variety of causes; and so may diminished transpiration, and either, in its more manifest states, is an important indication of disorder. The insensible perspiration may become sensible, owing only to a mild, warm, or humid state of the air; whilst the perspiration may not only be insensible, but this state of it may be much increased by more or less evaporation of the fluid in the skin by great dryness of the air.

2. *A.* When the halitus, or transpiration of the skin exceeds the evaporation of it in the atmosphere, sweat is formed; but, in addition to the substances contained in the perspiration, carbonic acid is also given out by it. In healthy persons, the skin exhales carbonic acid, nitrogen, and a watery fluid containing small quantities of the following substances: — 1st. Matters soluble in ether: traces of fat, sometimes including butryic acid.—2d. Substances soluble in alcohol: alcoholic extract, free lactic and acetic acids, chloride of sodium, lactates and acetates of potash and soda, lactate or hydrochlorate of ammonia.—3d. Substances soluble in water: watery extract, phosphate of lime, and an alkaline sulphate.—4th. Substances insoluble in water: desquamated epithelium, and phosphate of lime with a little peroxyde of iron.

3. Carbonic acid and nitrogen gases are exhaled in constant, but in varying proportions. COLLARD DE MARTIGNY states, that they are exhaled in the greatest quantities after meals and violent exertion; and that vegetable food causes an excess of carbonic acid, and an animal diet an excess of nitrogen. It may be regarded, with EDWARDS, that the physical exhalation of the skin is pure water and these gases; and that the organic function of the skin is the elimination of the above substances. (§ 2.) The proportion and amount of these matters vary much in different races of men. From several experiments, made many years ago on the Negro, I found that the gaseous exhalation from the skin, as well as the solid matters contained in the perspiration, especially the former, was much greater in this, than in the white race; and that the function of the skin in the former was

more decidedly supplementary of that of respiration than in the latter. Indeed, the cutaneous function of the negro race is of a much more decidedly eliminating nature, than that of the white race.

4. Besides the perspiration, the skin furnishes, by means of its sebaceous glands or follicles, a substance consisting of stearin, albumen, extractive matter with olein, phosphate of lime, &c.

5. The eliminating function of the skin is suppressed or interrupted in many diseases, especially in inflammations, until suppuration commences, in the early stage of fevers, in scurvy, in diabetes, &c.; whilst it is more or less augmented in the sweating stage of agues, in some adynamic forms of fever, in pestilential cholera, in acute rheumatism, in the advanced stages of tubercular consumption, in internal abscesses, and in other colliquative maladies.

6. *B.* The perspiration may be variously changed in *quality* in several diseases, owing to the contamination of the blood by some specific animal poison, or by the combinations of elements or materials which are usually, in health, eliminated from the blood by the several emunctories, and which, when either of these emunctories become impaired in function, accumulate in the blood, and are evacuated, in different combinations or states, in the cutaneous exhalations. Thus the sweat of rheumatic and gouty persons is generally acid, whilst in putro-adynamic fever, and in scurvy, it has a putrid odour. The perspiration of persons affected with itch, is said to emit a mouldy odour, and that of syphilitic patients has a sweet smell. STARK states, that the sweat of scrofulous persons resembles the odour of sour beer. The perspiration of persons labouring under small-pox or measles, or pestilential cholera, or scarlet fever, is often so peculiar in each of these maladies, as to lead to the recognition of the disease by its scent alone. On entering a house in which cholera was present, I have recognised the malady by the odour of the effluvium from the patient before I have seen him. The sweat is not only abundant, but often presents an urinous odour, in suppressions of urine, or other obstructions of the urinary organs.

7. *The lactic acid*, which is the usual free acid of the perspiration, is generally much increased in acute rheumatism and gout, especially the former. Dr. PROUT found free *acetic acid* in the sweat of a person in hectic fever. STARK says, that lactic acid is increased in the perspiration during scrofula, rickets, and various cutaneous eruptions; and both it and acetic acid exist in the sweat of females during their confinements, and even during suckling. The putrid sweat in adynamic fevers probably contains *ammonia*. The *saline ingredients* of the perspiration may be much increased. Dr. PROUT observed the skin of a man in dropsy covered with a white crust of chloride of sodium after an abundant sweat. In cases of gout, of urinary concretions and urinary obstructions, the quantity of phosphate of lime, and of other salts, is more or less augmented.

8. *C.* The foregoing consists only of an increase of the *normal constituents* of the perspiration; but *abnormal constituents* may be present. ANSELMINO and STARK assert, that *albumen* may exist in the sweat in rheumatic fever, in putrid, gastric, and hectic diseases. *Blood* has been seen in the perspiration in scurvy, and in putrid and yellow fevers. *Uric acid* and *urate of soda* have been found in the sweat of persons suffering from gout and urinary calculi. *Bilin* and *biliphæin* have been found in the perspiration of jaundiced persons, and sometimes in those labouring under low, bilious, remittent fevers. This secretion has, in rare instances, been seen variously coloured, owing to the existence of certain colouring matters, as cyanurin, &c. *Fat* has been found in the sweat in some colliquative maladies.

9. Various *substances, foreign to the œconomy*, may have been taken into the body and appear in the perspiration, especially sulphur, mercury, iodine and its combinations, indigo, saffron, assafœtida, camphor, &c. But as regards these and various other substances which are carried into the circulation, and eliminated from it by the emunctories, it is difficult to determine, unless by well-planned experiments, how much of this elimination is performed by the skin, or by the pulmonary exhalation, or by the kidneys.

10. II. ALTERATIONS OF APPEARANCE AND STRUCTURE.—i. The *temperature* of the skin varies much in disease, and somewhat in different constitutions and temperaments. It is generally *below* the healthy standard in scurvy, in some states of chronic rheumatism, in paralysis especially in anæsthetic paralysis, and in pestilential cholera most remarkably. The temperature is very much *increased* in the early stages of most fevers, especially in those characterised by augmented vascular action, and when transpiration from the skin is much diminished, or altogether suppressed. In these cases, more especially in ardent fever and inflammations, and in some states of malignant fever, the skin is not only hot, but it also conveys the sensation of an acrid or burning heat, even above that which the actual rise of temperature should impart. In all inflammations and acute diseases, the heat of skin is increased, especially when the perspiratory functions are interrupted. The temperature of the skin is also greater than natural, when the blood is loaded with excrementitial elements, owing to diminished elimination by the kidneys, bowels, and skin, and more especially when the accumulation of these elements in the blood is attended by febrile or increased vascular action. It is also sometimes increased shortly before dissolution, probably owing to this state of the blood.

11. ii. *The colour of the skin* is variously changed in disease, and this change may be general, or in large patches, streaks, or in small spots or points. The change may consist either in absence of colour, or uncommon pallor, or in a deepening of the tint. All changes of colour arise from the quantity and quality of the blood circulating in the vessels of the cutis vera; or, in the opinion of ROKITANSKY, from the state of the epidermis, especially its inner, or Malpighian layer, from some change in its cells, or from some unusual pigment in them.

12. *A. Pallor* of the skin is owing either to excessive loss of blood, to exhausting maladies, or to the chronic deficiency of red globules, observed in spontaneous anæmia, and some states of dropsy. The pallor may be associated with a slightly greenish or etiolated hue, as in chlorosis. It arises, in rare instances, from a congenital deficiency of pigment in the dark races, as observed in Albinoes, or from an acquired defect of this

kind. This latter change—achroma—may occur in all races, is generally limited in extent, or consists of a number of spots, of various sizes, that gradually spread.

13. *B. Yellowishness* of the skin is one of the most common alterations of colour. The shade may be very pale or very deep, or the yellow may be mixed with green; and even a dark greenish hue may predominate. These shades of colour occur in the different states of jaundice, and are most frequently owing to biliary obstructions occasioned by disease of the liver, or gall-bladder, or of the gall-ducts. Various tints, varying from yellow to yellowish green, to a yellowish blue, seldom uniform in all places, or continuing of the same depth or shade, are observed in the courses of pestilential yellow fever, or hæmagastric fever, when the blood becomes much altered, and resemble the discolourations caused by contusions. This change occurs in large blotches, patches, streaks, &c., and is not limited to any one part of the body.

14. *C.* A *dark, sallow,* or *muddied aspect* of the skin is observed at an early stage of typhoid or adynamic fevers, and this appearance often increases as the disease advances. It is owing chiefly to the state of the blood produced by defective oxyganization, or by imperfect depuration by the emunctories. A hue resembling this, but deeper, or inclining to brown, or to brownish yellow, seems to be owing to the deposit in the epidermis of a pigment. It occurs most frequently in spots or in patches or streaks, very rarely over the whole surface. I have observed it in spots and patches in a lady, who many years previously was the subject of jaundice. The uniform embrowning of the skin, by exposure to the sun, the spotted stains or freckles—ephelis, and the liver-spots, connected with disorders of the biliary apparatus, or of the uterine functions, are modifications in the colouring matters retained by the epidermis. Rokitansky remarks, that the skin sometimes becomes dark, when, with neglect of it and indulgence in alcohol, are combined infiltration of the liver with fat, and a tallowy state of the sub-cutaneous layer of fat. The skin in this case feels fatty, soft, and velvety, like that of a negro; its colour proceeds from the deposition of a pigment, containing fat, in the deepest layer of the epidermis,—a fact of much interest, owing to the association it evinces.

15. *D. Redness* of the skin occurs in so diversified forms, and with so numerous shades of yellow, blue, brown, livid, copper or bronze colour, &c., as to elude precise description, unless in affections and alterations of which these colours are pathognomonic. Of the several congestions, inflammations, impetiginous, exanthematous, chronic and specific eruptions, these colours are severally characteristic. The redness passes into blue, or bluish yellow, even to black, after exudations of blood into the cutaneous tissue; as in the sugillations, ecchymosis, vibices, petechiæ, &c. of scurvy, purpura, maculated and malignant fevers.

16. *E. Blueness* of the skin is the characteristic of cyanosis, which is more or less general, although somewhat deeper in parts which are delicate and vascular, and in the extremities. When it is limited to particular parts, it is usually the result of congestion, or of cold. A transient blueness of various parts of the surface has been remarked in rare instances by Otto: but in small patches or spots this discolouration is not infrequent. A *deep leaden*, or bluish tint, attends the collapse of pestilential cholera, but it is deeper on some parts than in others, especially shortly before dissolution. It also appears, in a slighter degree, in the face and extremities, in threatened asphyxia from congestive pneumonia, general bronchitis, hydrothorax, and from congestion of the lungs. A blue tint, approaching to bronze, is sometimes produced in the skin by the protracted use of nitrate of silver, and remains permanent, or nearly so, during life.

17. *F.* A *blackish tint* is sometimes observed in aged cachectic persons, especially in the lower limbs, and extends over large portions of the skin. It has been called melasma, and is different from melanosis. Lighter shades of black, passing into a tawny, dirty grey, leaden hue, &c., are sometimes observed in connection with various acute and chronic diseases, characterised by extreme cachexia and dyscrasis of the blood and soft solids, especially pestilential and malignant maladies, scurvy, cancer, &c.

18. iii. *The texture of the skin* is often remarkably affected; and changes of texture are also attended and followed by alteration of colour.—*A. Anæmia* of the integuments is observed chiefly in universal anæmia, but it may affect the integuments of the extremities only. The skin is always pallid when anæmied; and the pallor presents a waxen hue when the skin is delicate, and the parts beneath are fat or œdematous.

19. *B. Congestion* of the skin is observed after death in the most depending parts. It is seen in some adynamic or malignant diseases, occasioning lividity, dark-redness, or a bluish or blackish tint, and is most manifest in parts most remote from the heart, and when mechanical obstructions of the circulation exist.

20. *C. The exudations of blood,* or small, circumscribed hæmorrhages, into the tissues of the skin, forming small spots or larger patches, or sometimes streaks, observed in purpura, in scurvy, and in petechial fevers, have been ascribed by Rokitansky to a higher degree of congestion of the skin; but however greatly these changes may be owing to the cause to which he imputes it solely, they depend more on impaired irritability of the extreme capillaries, on diminished vital cohesion of the tissues composing the skin, and on dyscrasis and other changes in the blood itself. (*See art.* Hæmorrhage, §§ 14—19.)

21. *D. Inflammations* very frequently attack one or more of the tissues composing the skin. They are sometimes idiopathic and substantive diseases, especially when produced by external or physical causes; but they are more frequently symptomatic, or caused by morbid conditions of the circulating fluids, arising from a superabundance of excrementitial elements and materials in the blood, or from a specific animal miasm or poison. Most of the chronic eruptions, or inflammations, depend upon morbid states of the blood, caused by impaired depuration by the kidneys, liver large bowels, or by the skin itself. Some of these inflammations may also appear as a morbid reflection on the skin of disordered actions of important internal viscera. Inflammations of the skin are either limited to spots or to patches, more or less numerous, or diffused over large tracts. They sometimes are seated only, or chiefly, in the

external layer and papillæ, as in *erythema;* and at others, the deeper layer, and the whole thickness of the corium, are affected, as in *phlegmonous* inflammation. From these forms, there are numerous transitions and associated changes, according as one or more of the layers or tissues composing the integuments, or as the subjacent cellular tissues, are implicated, and as the disease may extend in spots or patches, or become more or less diffused. Inflammations of the skin, whether erythematous, exanthematous, impetiginous, phlegmonous, furuncular, gangrenous or ulcerative, or acute, chronic or specific, have been so fully described in the numerous articles or heads to which they severally belong, that I cannot devote further space to their special consideration, more particularly as there is nothing of importance which I can add to what has already been advanced respecting them individually.

22. E. *Adventitious growths* in the skin have been described chiefly in respect of their internal characters, and often commence in the subjacent cellular tissue. — *a. Molluscum simplex,* or soft, wartlike growths, attached by a pedicle, consists of saccular dilatations of the corium, and contains cellular tissue, and sometimes also fat. — *b. Fleshy excrescences,* which often form on the nose, are composed of a luxuriant growth, or hypertrophy, of the corium, and of cellular tissue.

23. — *c. Condylomata* commonly form about the organs of generation and the arms, especially in the mucous membrane of the former. They are either soft, or more or less firm; and in their form they are either broad, or rounded, or pointed. They are often attached by a pedicle, their extremities resembling a mulberry, a cauliflower, or a cock's comb. They are composed of an investing layer of epithelium, and of newly-formed cellular tissue. They originate in the corium, where they take deep root. With these, ROKITANSKY believes, that certain tumours regarded as syphiloid, the Radesyge, &c., may be connected.

24. *d. Fatty tumours* are most frequently congenital, but they are sometimes developed at later periods of life. One only may exist, or there may be several on different parts of the body. They are rounded, often truncated, and attached by a pedicle, and they sometimes reach a very considerable size. They consist of a prolongation of skin, as if protruded by an inclosed lobule of fat, which is continuous, by a sort of pedicle, with the subcutaneous, adipose stratum. The epidermis covering them is sometimes dark-coloured, owing to the pigment it contains, and hair occasionally grows upon them. When congenital, it is often associated with nævus in other parts of the skin.

25. *e. Fibrous tissue* occurs in the skin after repeated or chronic attacks of inflammation, and in the cicatrices after burns and other injuries. The alteration termed *cheloid* by ALIBERT, is connected with the fibrous; for it appears to consist of a fibrous callus, and with that appearance its external cicatrix-like aspect corresponds. ROKITANSKY describes this latter alteration, — the cheloid — as consisting of several varieties, — of a simple hardness or callosity of the skin; or of a flat, somewhat raised, or a depressed hardness; or of a cord-like hardness, and of a white, or pale, or rose-colour. In either form, it may terminate in white or red elevated lines or processes. It is of inconsiderable extent, and occurs, for the most part singly, at the upper part of the trunk, on the extremities, or on the face. It rarely exists in large numbers, and it seldom ulcerates; when it does so, it becomes indolent and difficult to heal. It is generally connected with constitutional disorder, but it is not truly cancerous.

26. *f. Bony deposits* are extremely rare in the skin. ROKITANSKY once found a bony plate, which was oval, yellowish, hard, and rugged, of the size of a half-crown, in the substance of a scar on the trunk. It corresponded precisely with the osseous deposits occurring in fibrous exudations on serous membranes.

27. *g. Vascular nævi—teleangiectasis*—are generally congenital. They sometimes form deep or bluish red stains, of various sizes and shapes; occasionally red tumours, resembling cherries, strawberries, or mulberries, and often present a transient swelling, — *erectile* or *splenoid tumours* of some authors. They also commence, in rare instances, after birth, or at later periods, and are at first, or even subsequently, not malignant; but they may, in the cancerous diathesis, be converted into malignant growths — into a fungus hæmatodes cutis.

28. *h. Melasma,* or the blackish discolourations observed chiefly in aged, decrepit, and cachectic persons, occurs either diffused in parts of the surface of the body, especially the lower extremities, rarely over the whole surface, or concentrated in small raised spots, or berry-like tumours, on the trunk or face. In the former, the colouring matter is diffused on the surface of the cutis; in the latter, in the substance of the cutis also. Melasma should not be confounded with melanosis, the cancer melanodes.

29. *i. Tubercle.*—It is doubtful whether or no true tuberculosis affects the skin in a way corresponding to that observed in mucous, serous, and parenchymatous structures. Tubercles, however, appear in ulcers affecting the cutaneous expansions of scrofulous persons, but most frequently in a softened form, or in that of puriform tubercular matter. An ulcerative softening of the skin, in connection with tubercular deposits in the subcutaneous cellular tissue, or in lymphatic glands, is a common occurrence.

30. *k. Cysts* do not occur in the cutis vera; but the sebaceous glands often degenerate into cysts of considerable size. Cysts also form in the subjacent cellular tissue, and become closely connected with the skin. These, as well as morbidly-enlarged sebaceous follicles, commonly contain cholosterine. This substance has also been met with as a stratum on the surface of open ulcers of the skin.

31. *l. Cancer* and cancerous ulceration are often met with on the skin. When cancer commences in the subcutaneous or glandular tissues, particularly the mammæ and lymphatic glands, it generally soon implicates the skin, and becomes, from an early period, very closely connected with the cutis. But cancer often also originates in the skin, in the form either of fibrous or scirrhous cancer, or of medullary cancer.

32. (*a.*) *Fibrous cancer* of the skin generally assumes the form of a tuberculated or rounded nodule, sometimes flattened, or even depressed, below the surface of the skin, and forming an umbilicated fossa. It is generally single, about

the size of a hempseed, pea, or small nut, firmly fixed, and as hard as cartilage. Sometimes it is smooth and shining externally, occasionally covered by a hard, laminated crust of cuticle, and often darker than the surface around. It occurs chiefly on the face, lips, and nose, but occasionally on other parts of the body. It is commonly the primary cancerous growth, and often the first of a series of cancerous formations in different organs. In some instances it reaches a considerable size, growing into a tuberous mass, projecting beyond the skin. (Rokitansky.)

33. (*b.*) The *medullary kind* is usually a secondary formation, and consequent upon large cancerous growths, which first appear just beneath the skin, or which involve the subcutaneous structure first, and then the skin itself. In either case it grows in the skin in isolated or confluent nodules near the primary mass. It sometimes also appears in the skin, after it has been localised in one or more organs. The nodules which it forms in the cutis are mostly numerous, and about the size of peas or hazel-nuts; they are scattered over the body, especially over the trunk, and generally near similar growths in the subcutaneous cellular tissue. In the case of a boy, about 14 years of age, for whom I was consulted, I counted upwards of twenty thus disseminated. It is characterised as a whitish, or whitish red growth, which is sometimes tolerably firm and lardaceous, or medullary, and occasionally looser, softer, and resembling cerebral substance, or even much softer and diffluent; and it often grows to a considerable size. It may also contain black pigment, and thus constitute *cancer melanodes* of the skin. The layer of skin above the nodule becomes stretched, and shining or transparent, or rough from the loss of its epidermis. Sometimes the elementary particles of the disease are deposited in vascular *nævi*, or, as the deposition takes place, the vessels of the part are excessively developed, and a cancerous structure, of uncommon vascularity, is the result, or *fungus hæmatodes* of the skin. Rokitansky considers *chimney-sweepers' cancer*, and Alibert's *eburnated cancer of the skin*, as special varieties of this disease.

34. *α. Chimney-sweepers' cancer* appears to be medullary. It begins in the scrotum as a tolerably firm, small nodule, or warty excrescence, which after some time becomes red, excoriated, moist, and covered by a cortex of thickened cuticle. The papillæ beneath enlarge, and the whole becomes an ulcer, with irregular, hard, and raised edges. Fresh nodules form around the original one, undergo the same changes, and enlarge the disease superficially. The nodules are developed into fungous cauliflower excrescences, and the disease extends deeply, until the dartos, the tunica vaginalis, and testicle are successively implicated, and the gland itself ulcerates, while the adjoining lymphatic glands and vas deferens degenerate up to the abdominal cavity.

35. *β. Eburnated cutaneous cancer* is a secondary degeneration of the cutis over a subcutaneous scirrhous mass. The skin is white, glistening, indurated, partially transparent, and immoveable, over the firm or hard mass. This change of the skin evidently belongs to the fibrous form of cancer, as it is always connected with the subjacent scirrhus. *Cancerous ulceration* supervenes, at a sooner or later period, upon all the forms of cutaneous cancer, and generally proceeds as I have described when treating of Cancer. (*See that art.* § 11. *et seq.*)

36. *m. Parasites.*—Several kinds of *pediculi* are found on the skin, especially on parts covered by hair; and the *acarus scabiei*, and probably other species of the genus acarus, occur on, and in eruptions of, the skin. Various fungi also exist in certain chronic eruptions on the cutis, as in cases of *tinea favosa*, and *sycosis*. The subcutaneous cellular tissue not infrequently lodges the *filiaria medinensis*, especially in certain climates, as the western coast of Africa, &c.

37. III. The Sebaceous Glands, or follicles, and their ducts, are often the seats of various disorders; and in many of the affections of the skin, and in some of the exanthemata, especially small-pox and measles, they are especially implicated. But they are more manifestly the seat of disorder, when an accumulation of thin secretion takes place in them, owing to an impaired power of discharging it, or of throwing it off, or to obstruction of their ducts. In the former state, or impaired power of excretion, the duct is enlarged, and filled with the accumulated secretion, forming what has been termed *maggots*. In the latter state, the secretion accumulates in the follicular sac itself, and produces a rounded tumour, from the size of a millet-seed to that of a hazel-nut, or even larger. The matter thus accumulated consists of a whitish substance, of a pulpy consistence, viscid like fat, and resembling adipocire. In many cases it is very offensive in its odour, and irritating to the containing tissues, thereby producing inflammation, as in acne, sycosis, &c. Calcareous deposits, and even horny excrescences, may even originate in those glands in very rare instances. The secretions of the sebaceous follicles may be either deficient in quantity, altered in quality, or excessive in amount; and, in either case, occasion a more or less manifest disorder of the functions of the skin. In the *first* of these conditions, the skin will be dry and harsh; in the *second*, the exhalation from it will be more or less offensive; and in the *third*, it will be unctuous, humid, and often also offensive to the smell.

38. IV. The Cuticle and Nails partake in several of the diseases of the skin.—(*a.*) The *cuticle* is sometimes very thin and delicate throughout, owing to original formation, but more frequently only in parts, especially in those where it has been recently thrown off. It is much more frequently formed in excess; and then either its outer layers are separated in the form of bran, scales, scurf, or laminæ, or it accumulates and adheres, producing callosities, corns, or crusts, of various forms and sizes, occasioning more or less uneasiness, or pains of the subjacent parts.

39. *α.* The *colour* of the skin partly resides in the deeper layers of the cuticle, which may contain a yellowish, brownish, or a black pigment, distinguishing, when congenital and general, particular races or individuals. But the colouring may be acquired, and limited to particular spots or parts, or be more or less diffused, and indicate disorders of important internal organs, or a cachectic condition of the whole œconomy. It is always in excess, in a remarkable degree, in congenital nævi. A complete absence of the colouring matter is congenital in albinoismus, and is acquired in achroma or vitiligo. The former may be general

or partial; the latter is always partial at first, but it may become more general.

40. *β*. The epidermis is often drier and harsher than natural, it is rarely more moist. It presents the former states in various cutaneous diseases, in which it is either thrown off in the form of scales, or it accumulates, and occasions cracks or fissures, extending through it into the cutis. Accumulation of the epidermis, or of the cells composing this structure, is often simultaneous with, if not the consequence of, excessive development of the papillæ of the cutis. The morbid results of these conditions are one or other of the following: — 1st. *Callosity*, tyloma, or simple accumulation of epidermoid cells, in the form of strata, successively formed underneath, the more recently produced extruding the older; — 2d. *Corn*, or clavus, a circumscribed callus, projecting into the corium, and occasioning more or less pain; — 3d. *Crusts*, scutes, or scutiform accumulations of laminæ of diseased epidermis, presented by the scaly eruptions; — 4th. *Horny growths* proceed either from a diseased portion of skin, or from a sebaceous follicle; and are met with generally on the scalp, and are usually single, much more rarely two or more are observed. They are of various dimensions, from half an inch to several inches in length, and as thick as, or thicker than, a finger; straight, or curved, or crooked; attached by a broad base, and of a dark colour. They have been observed in some cases to be regularly shed at intervals; and when removed, they are reproduced, if the portion of skin producing them be not destroyed.

41. (*b*.) The *nails* often present the peculiarities possessed by the parents, or evince hereditary characters. Their growth may be excessive or deficient; or they may be misshapen or thick, twisted, or curved. They may be everted or inverted; or become excessive in length, or much shortened. Eversion is often observed in psoriasis, when shortening, thickening, and induration are often co-existent with it. The nails are then discoloured, and are also drier and more brittle than natural. Incurvation of the nails, sometimes with elongation, is common in tubercular consumption. The most deformed states of the nails are observed in connection with the scaly eruptions. (See the articles on these eruptions, and that on the HAIR.)

42. V. CLASSIFICATION OF THE DISEASES OF, OR AFFECTING THE SKIN. — The arrangement of diseases of the skin must necessarily be conventional. All disorders of the animal œconomy, — whether functional or structural, whether local or constitutional, whether internal or external, — glide insensibly into those more intimately allied to them in situation, in the nature of the tissues affected, in constitutional disturbance, and in the local and general characters of the affection; and present no constant lines of demarcation by which they can be accurately separated from those which they most resemble. Morbid actions, even in their most visible and palpable forms, evince none of the unalterable features characterising the products of the vegetable and animal kingdoms. These products belong to distinct genera and species, and each consists of a specific being; but morbid actions are incalculably diversified, and ever varying, passing insensibly, and more or less rapidly, into as varying states of visible disease, and ultimately into not merely manifest but also palpable organic changes, when the earlier phases or grades of morbid action are not arrested by vital resistance, or by the aid of medicine.

43. Of the more or less *artificial classifications* of diseases of the skin, furnished by PLENCK, WILLAN, BATEMAN, PLUMBE, RAYER, WILSON, and others; or of the *natural arrangements* attempted by ALIBERT and PAGET, most of the former being modifications of the classification of PLENCK or WILLAN, it is unnecessary to take particular notice. An artificial arrangement involves frequent repetitions when treating of this class of diseases,—presents as unvarying distinctions what are continually undergoing changes, and are neither peculiar nor constant,—and insufficiently recognises constitutional disturbances, specific taints, and contaminating causes. Natural classifications, whilst they are based on natural alliances arising out of constitutional conditions, and specific causes or contaminating influences, retain those visible or palpable distinctions which actually exist, and present them for the purposes of diagnosis and of rational treatment. The artificial plan comprises, under the same order, eruptions which require the most opposite indications and means of cure; whilst the natural arrangement associates those maladies in one family or order, for which the same indications and remedies are found most beneficial. Without entirely neglecting the classifications of ALIBERT and PAGET, the following has been devised with a much stricter adhesion to constitutional and natural alliances than these writers have shown, and with a due recognition of the causes, contaminating characters, and ultimate changes, which distinguish these diseases individually, and which connect each group and family with those preceding or following it. The reader will perceive, by comparing the following arrangement with those of the authors above mentioned, in what it differs, as well as in what it agrees with them.

44. ORDER, FAMILY, or NATURAL GROUP I. DYSCHROMATA — *Maculæ*. — Changes of colour, or excess or deficiency of the colouring matter of the skin, occurring congenitally, or at any period of life, generally in spots or large patches, and frequently connected with slight disorder of the digestive organs, or of the general health.

45. GENUS i.—PANNUS—EPHELIS, — *Chloasma*. — Consisting of spots, patches, &c., of various forms, of a darker or deeper hue of the skin, owing to increase of its colouring matter, occurring at any period of life. — *Spec.*: 1st. *P. lenticularis*; — 2d. *P. hepaticus*; — 3d. *P. melaneus*; *4th. P. carateus*. (*See art.* EPHELIS.)

46. GENUS ii. — ACHROMA. — White spots or patches scattered over the skin, or limited to a part, the decolouration being remarkable, and often attended by temporarily impaired sensibility, owing to deficient or interrupted arterial circulation, when the extremities are its seat. — *Spec.*: — 1st. *A. Vitiligo*; — 2*d*. *A. Congeniale*.

47. ORDER II. DERMATITES — D. SIMPLICES — ECZEMATA — *Eczematosæ*. — Inflammations of the skin, attended by redness, itching, stinging, slight swelling, or an eruption of papulæ, vesicles, bullæ, pustules, or tubercles; often being of local origin, but much more frequently depending upon disorder of the digestive and eliminating organs, and consecutively of the circulating fluids; and observing either an acute, or sub-acute, or

chronic course. They are not limited to any part of the cutaneous expansions; they may affect one or more of the cutaneous tissues, or even extend, more or less, to the subjacent cellular substance; and they are not contagious.

48. Genus i. — Erythema. — Superficial redness, varying in extent, with slight elevation, terminating in furfuration and desquamation, or, in cachectic habits, from neglect of cleanliness, or improper treatment, in excoriation or ulceration. — *Spec.*: 1st. *E. spontaneum*; — 2d. *E. endemicum*; — 3d. *E. epidemicum*; — 4th. *E. Intertrigo*; — 5th. *E. Paratrimma*; — 6th. *E. Pernio*; — 7th. *E. per Adustionem.* (*See art.* Erythema.)

49. Genus ii. — Roseola — *Rose-Rash.* — Rose-coloured, irregular, and slightly elevated patches of the skin, transient and not papular; passing into deeper roseate hues as they disappear, generally preceded or attended by slight fever, or gastro-intestinal disorder. — *Spec.*: 1st. *R. æstiva*; — 2d. *R. autumnalis*; — 3d. *R. annulata*; — 4th. *R. infantilis*; — 5th. *R. symptomatica vel associata* — of small-pox, of cow-pox, of fever; of gout, of the consecutive fever of pestilential cholera. (*See art.* Rose-Rash.)

50. Genus iii. — Urticaria. — An eruption of irregular, prominent patches or wheals, of various sizes, generally transient, and attended by burning, tingling, and itching, and by slight fever and disorder of the digestive functions. — *Spec.*: 1st. *U. febrilis*; — 2d. *U. evanida*; — 3d. *U. tuberosa.*

51. Genus iv. Lichen — *Licheniasis.* — An eruption of clustered or irregularly-disseminated papulæ, attended by itching, stinging, &c., and slight febrile disturbance, or gastro-intestinal disorder, terminating in desquamation, and liable to recur. — *Spec.*: 1st. *L. simplex*; — 2d. *L. Strophulus*; — 3d. *L. agrius, vel L. tropicus.* (*See art.* Lichen.)

52. Genus v. — Prurigo. — A papular eruption, the papulæ being larger than those of lichen, of nearly the colour of the skin, generally appearing on the outer surface of the limb, attended by burning and intolerable itching, &c. — *Spec.*: 1st. *P. mitis*; — 2d. *P. formicans*; — 3d. *P. senilis.* (*See art.* Prurigo.)

53. Genus vi. — Eczema. — An eruption of minute vesicles, crowded together, non-contagious, and terminating by the absorption or evaporation of a thin fluid, or by excoriations, with serous exudations, concreting into crusts. — *Spec.*: 1st. *E. simplex*; — 2d. *E. rubrum*; — 3d. *E. impetiginodes*; — 4th. *E. mercuriale.* (*See* Eczema.)

54. Genus vii. — Herpes. — An eruption of vesicles, distinctly but irregularly clustered, upon inflamed bases, extending beyond the margins of the clusters, attended by tingling, concreting into lamellar scabs. — *Spec.*: 1st. *H. phlyctenodes*; — 2d. *H. circinnatus*; — 3d. *H. Zoster*; — 4th. *H. præputialis*; — 5th. *H. Iris.* (*See art.* Herpetic Eruptions.)

55. Genus viii. — Bullæ. — An elevation of the epidermis by an effusion of serum, often passing into a sero-puriform fluid, into large vesicles or blebs, which are generally round or oval, have a broad base, and vary in size from that of a pea to that of an egg. — *Spec.*: 1st. *Pemphigus*; — 2d. *Rupia.* (*See arts.* Bullæ, Pemphigus, and Rupia.)

56. Genus ix. — Ecthyma. — An eruption of phlyzaceous pustules, always distinct, seated on a hard, inflamed base, and followed by dark scabs, leaving slight cicatrices or red stains, which disappear after some time. — *Spec.*: 1st. *E. acutum, vel E. vulgare*; — 2d. *E. chronicum, vel E. cachecticum.* (*See art.* Ecthyma.)

57. Genus x. — Impetigo — *Mellitagra.* — The eruption of psydraceous pustules, commonly grouped in clusters, sometimes distinct, and forming yellowish, rough incrustations; attended by itching, but by little or no fever. — *Spec.*: 1st. *I. simplex*; — 2d *I. favosa, vel Porrigo favosa*: — 3d. *I. eczematosa*; 4th. *I. rodens.* (*See art.* Impetiginous Affections.)

58. Genus xi. — Acne — *Varus* — *Adenodermatitis.* — A pustular affection, appearing chiefly about the period of puberty in both sexes, occurring as small, isolated pustules, with hard, deep-red bases, leaving circumscribed, indolent, and hard tumours, and seated chiefly in the sebaceous follicles, most frequently of the face, neck, shoulders, and breast. — *Spec.*: 1st *A. simplex*; — 2d. *A. indurata*; — 3d. *A. rosacea.* (*See art.* Acne.)

59. Genus xii. — Furunculus. — Inflammation limited superficially, but extending to all the cutaneous tissues and subjacent cellular substance, forming a hard, conical tumour, of a dull red colour, varying from the size of a pea to that of a pigeon's egg, terminating in suppuration, with the evacuation of a membranous slough, or of the membrane that inclosed the matter. — *Spec.*: 1st. *F. vulgaris*; — 2d. *F. asthenicus*; — 3d. *Hordeolum*, or *Stye.*

60. Genus xiii. — Carbunculus. — Circumscribed, hard, round, and painful swelling, seated in the cellular tissue of the skin and the subcutaneous tissue; at first of a livid red colour, afterwards black, or of a deep livid hue in the centre or throughout, and covered by lenticular vesicles; terminating in gangrene or sloughing. — *Spec.*: 1st. *C. sporadicus*; — 2d. *C. endemicus*; — 3d. *C. symptomaticus.* (*See art.* Furuncular Eruptions.)

61. Order III. — Squamosæ — *Dermatites squamosæ* — *D. serpiginosæ* — *D. chronicæ* — *Serpigines.* — Chronic affections characterised by the production, on the surface of the skin, of inorganic, laminated scales, of a whitish grey colour, dry, friable, and slightly elevated above the skin, which remains red and dry when the scales fall off. They are generally slowly developed, spread, and continue for months, or even for many years. They are not contagious.

62. Genus i. — Pityriasis. — A superficial affection, implicating chiefly the cuticle, characterised by a copious desquamation and renewal of this tissue, and, although it may appear on any part, affecting chiefly parts covered by hair. — *Spec.*: 1st. *P. Capitis*; — 2d. *P. Palpebrarum*; — 3d. *P. Labiorum*; — 4th. *P. palmaris et plantaris*; — 5th. *P. præputialis et pudentalis*; — 6th. *P. versicolor*; — 7th. *P. nigra.* (*See art.* Pityriasis.)

63. Genus ii. — Psoriasis. — *Lepriasis* — Patches of chronic inflammation of the skin, with slight elevations changing into scales, — those of *psoriasis* being of different sizes, with irregular margins, and the centres not depressed; those of *Lepriasis* being more or less rounded, slightly depressed in their centres, and their margins raised

and reddish.—*Spec.:* 1st. *Psoriasis guttata*; — 2d. *P. diffusa*; — 3d. *P. inveterata*; — 4th. *P. lepræformis* — *Lepriasis*. (*See arts.* Psoriasis and Lepriasis.)

64. Order IV. — Hæmatodes — *Sanguineous Exudations.* — Infiltrations of blood in the cutaneous and subcutaneous tissues, generally without manifest elevation of the surface, owing to impaired vital cohesion of these tissues, and of their capillaries, and to alteration of the blood.

65. Genus i. — Purpura. — Small, distinct, purple specks or patches in the skin, attended by languor and debility, generally without fever. — *Spec.:* 1st. *P. simplex*; — 2d. *P. hæmorrhagica*; — 3d. *P. urticans*; — 4th. *P. symptomatica vel associata*—of exanthematous and continued fevers. — (*See art.* Purpura.)

66. Genus ii. — Scorbutus. — The appearance of patches or blotches of a livid, reddish, or purplish hue, chiefly on the lower limbs, with swelling and bleeding of the gums, great debility, and pains, and contractions of the lower extremities, &c. — *Spec.:* 1st. *S. sine Febre*; — 2d. *S. febrilis*. (*See art.* Scurvy.)

67. Genus iii. — Petechiæ — *Ecchymoses.* — Small spots, generally of a reddish colour, but often livid, violet, or blackish, scattered over the surface of the skin, sometimes resembling flea-bites, or small freckles, remaining a longer or shorter time, varying from an imperceptible point to the size of a hempseed, occurring with or without fever, but most frequently in the advanced stages of adynamic fever. — *Spec.* 1st. *P. primariæ, vel P. sine Febre*; — 2d. *P. secundariæ*.

68. Order V. — Exanthemata — Febres Exanthematicæ — Dermatites Exanthematicæ — Eruptions of various kinds, preceded by fevers of specific natures and fixed durations, the eruptions being generally also of determinate durations, spreading by infection and contagion, or by both—by specific contaminating miasms, or animal poisons, and generally affecting the œconomy only once. (*See arts.* Exanthematous Diseases and Infection.)

69. Genus i. — Rubeola — Morbilli — *Measles.* — Fever, with frequent sneezing, coryza, redness of the eyes, lachrymation, followed generally on the fourth day by a crimson rash, consisting of stigmatised dots, slightly elevated, on the face, neck, breast, and trunk, usually desquamating on the seventh, occurring frequently epidemically, spreading by infection, and affecting the system only once. — *Spec.:* 1st. *R. vulgaris*; — 2d. *R. complicata*; — 3d. *R. maligna*; — 4th. *R. sine Catarrho*; — 5th. *R. sine Exanthemate*. (*See art.* Measles.)

70. Genus ii. — Scarlatina — *Febris Scarlatinosa* — A continued fever, on the second or third day of which, a scarlet efflorescence generally appears on the fauces, face, and neck, spreading over the body, terminating in desquamations from the fifth to the seventh day, frequently attended by affection of the kidneys, and followed by dropsy; often occurring epidemically, propagated by infection, and attacking the system only once. — *Spec.:* 1st. *Scarlatina Hominum.* — *Var.:* *a. S. simplex*; — *b. S. anginosa*; — *c. S. maligna*; — *d. S. sine Exanthemate*; — *e. S. latens*. (*See art.* Scarlet Fever.) *Spec.:* 2nd. *Scarlatina rheumatica, vel S. r. epidemica* (*see art.* Scarlatina Rheumatica); — 3d. *Scarlatina Equi*[*], *vel S. Equi epidemica*; — 4th. *Scarlatina Canis*.

71. Genus iii. — Febris Exanthematica — *Typhus* — *Typhus exanthematicus.* — Typhoid, low, or adynamic fever, attended by stupor, vertigo, confusion of ideas, delirium, or typhomania; by a reddish, papillar eruption on the trunk of the body and limbs; propagated by infection, appearing epidemically, and seldom affecting the system a second time. — *Spec.:* 1st. *F. Typhoides*; — 2d. *Typhus contagiosus.* (*See art.* Fever, Typhoid and Typhus, § 485. *et seq.*)

72. Genus iv. — Variola — Small-Pox. — Fever, commencing with shivering, and, after forty-eight hours, or three days, attended by an eruption of red points, passing successively into pimples, acuminated vesicles, flattened and umbilicated vesicles, pustules, and hard brown scabs; ceasing on the development of the eruption, and returning when the eruption has reached its acme, or from the eighth to the eleventh day; the falling off of the scabs, from the twelfth to the twenty-fourth day, leaving behind them dark pits or marks; highly contagious, and affecting the system only once. — *Spec.* 1st. *Variola Hominum.* — *Var.:* *a. V. discreta*; — *b. V. confluens*; — *c. V. sine Variolis.* — *Spec.* 2d. *Variola Animalium.* — *Var.:* *a. V. vaccina*; — *b. V. ovilis, vel Clavus.* — *Spec.* 3d. *V. varioloidea, vel Variola Hominis anomala.* (*See arts.* Small-Pox and Vaccination.)

73. Genus v. — Varicella — *Chicken-pox.* — an eruption of semi-transparent, glabrous vesicles, with red margins, following and attended by a slight attack of fever; the vesicles seldom passing into suppuration, but breaking on the third or forth day, concreting into small puckered scabs, and leaving no cicatrices; affecting a person only once. — *Spec.:* 1st. *V. lentiformis*; — 2d. *V. coniformis*; — 3d. *V. globularis.* (*See art.* Chicken-Pox.)

74. Genus vi. — Miliaria — *Sudamina.* — An eruption of whitish or pale reddish vesicles, the size of a millet-seed, in the course of severe infectious fever; the vesicles being distinct, containing a serous fluid, of a whitish, or reddish, or purplish hue, bursting in two or three days, and terminating in a scurfy desquamation. — *Spec.:* 1st. *M. simplex*; — 2d. *M. abnormis.* (*See art.* Miliary Eruptions.)

75. Genus vii. — Erysipelas. — Asthenic inflammation of the integuments, consequent upon febrile disorder and a morbid state of the blood, affecting the skin or scalp more or less extensively, with a diffused swelling disposed to spread, propa-

---

[*] I have lately had reasons, indeed evidence, for the following inferences: — 1st, That Scarlatina was originally a disease of the horse; and that it formerly occurred, and has even recently occurred, epidemically, or as an epizooty among horses; 2d, That it was communicated in comparatively modern times from horses to man; 3d, That it may be, and has been communicated also to the dog.

Whilst this article was passing through the press, and after the preceding part of this note was printed, Mr. Percival, Veterinary Surgeon to the 1st Regiment of Life Guards, and author of the very able and well known work on the Diseases of the Horse, kindly furnished me with additional evidence in support of the opinion I have stated at this place, and when treating of Scarlet Fever. (*See that article*, §§ 90., &c.) Mr. Percival also referred me to the second volume of his work, where Scarlatina in the Horse is mentioned.

gated by infection when circumstances favour the operation of the poisonous miasm. — *Spec.:* 1st. *E. simplex;* — 2d. *E. complicatum.* (*See art.* Erysipelas.*)

76. Order VII. — Dermatites contagiosæ — D. specificæ contagiosæ — Aischrodes — *Eruptiones contagiosæ* — *Contaminating Eruptions.* — Eruptions propagated by direct or mediate contact, of indeterminate, but generally prolonged duration, often contaminating the whole frame; and certain of them tending to fatal terminations.

77. Genus i. — Scabies — *Itch.* — An eruption of distinct, slightly acuminated vesicles, attended by constant itching; the eruption varying in character, but often concealing a parasite or *acarus*, either causing, or produced by it, unattended by constitutional disturbance. — *Spec.* 1st. *S. Hominis;* — *Var.: a. S. H. vesicularis;* — *b. S. papuliformis;* — *c. S. lymphatica;* — *d. S. purulenta;* — *e. S. cachectica.* — *Spec.* 2d. *Scabies Canis.* (*See art.* Itch.)

78. Genus ii. — Sycosis — *Mentagra.* — A pustular eruption of a pale yellow colour, seated chiefly in the hairy parts of the face, as the chin, upper lip, cheeks, &c., affecting the hair follicles and connected tissues, bursting in the course of some days, and producing brownish crusts, which after one or two weeks leave indolent purplish tubercles; the pustules being renewed in different parts, thus continuing for an indeterminate period, and apparently propagated by a parasitic plant, or cryptogamic formations. — *Var.:* 1st. *S. simplex;* — 2d. *S. contagiosum.* (*See art.* Sycosis.)

79. Genus iii. — Favus — Tinea — *T. maligna* — *Porrigo* — *Ring-Worm.* — A specific chronic inflammation, seated chiefly in the hair-follicles, exuding a peculiar yellowish substance, which accumulates and forms a cup around the base of each hair, the aggregation of a number of these resembling the cells of a honey-comb. The hair of the diseased follicles is altered, imperfectly nourished, and falls out; and if the disease be not arrested, the subjacent tissues become affected. This contaminating eruption is usually seated in the scalp, sometimes extending to the face, neck, and other parts of the body, and is communicable to any part of the skin. — *Var.:* 1st. *F. dispersus;* — 2d. *F. confertus.* (*See art.* Tinea.)

80. Genus iv. — Pustula Maligna — *Contagious Anthrax.* — A large vesicle filled with a sanious fluid, seated over a lenticular induration, which is speedily surrounded by an erysipelatous areolar swelling, which soon becomes gangrenous, and contaminates the circulating fluids; caused by the contact of a septic animal poison, and communicable from person to person, and from the lower animals to man. — *Spec.:* 1st. *P. M. Hominis;* — 2d. *P. M. Animalium.* (*See art.* Pustule, Malignant.)

81. Genus v. — Glanders† — Farcy — *Farcy-Glanders.* — Fever of a low and malignant character, attended by chancry sores of the membrane of the nose, and a profuse, offensive discharge, and by pustular eruptions, or tubercular, gangrenous ulcers, in various parts of the cutaneous surface, produced by the contact of the poisonous matter. — *Spec.:* 1st. *Simple Acute Glanders;* — 2d. *Acute Farcy Glanders;* — 3d. *Simple Chronic Glanders;* — 4th. *Chronic Farcy Glanders.* (*See art.* Glanders.)

82. Genus vi. — Syphilis — *Syphilitic Eruptions* — *Venereal Eruptions.* — A distemper contracted, generally by impure contact, and characterised, externally, by copper-coloured spots, or by pustules, vegetations, excrescences, ulcerations, swellings, tumours, or imposthumes; internally, by pains in the bones or periosteum, or by caries. — *Spec.* 1st. *S. eczematosæ.* — *Var.: a. lenticularis;* — *b. papularis;* *c. vesicularis;* — *d. pustularis;* — *e. tubercularis.* — *Spec.* 2d. *S. squamosa.* — *Var.: a. Leprosa;* — *Psoriasis.* — *Spec.* 3d. *S. vegetans.* — *Var.: a. verrucosa;* — *b. Condyloma;* — *c. Cauliflora;* — *d. Frambœsia;* — *e. Crista-Galli.* — *Spec.* 4th. *S. exulcerans.* — *Var.: a. serpiginosa;* — *b. fissata;* — *c. excavata.* (*See art.* Syphilitic Affections.)

83. Genus vii. — Mycosis. — A contagious disease, consisting of fungous excrescences, occurring chiefly on the face, hairy scalp, or about the organs of generation, resembling a mulberry or strawberry, exuding a yellowish, fœtid, and viscous humour, sometimes forming tumours of considerable size, and often attended by pains in the bones, by hoarseness, coryza, or ozœna, ulceration of the tonsils, &c. — *Spec.:* 1st. *M. Frambesioides, Frambœsia;* — 2d. *M. Molluscum, Amboyna-pox;* — 3d. *M. syphiloides, Sibbens,* &c.

84. Order VIII. — Leprodes — *Leprous Eruptions.* — Morbid degenerations of the skin, depending upon constitutional vice, attended by diminution of the sensibility of the diseased surface, by general hypertrophy of the cutaneous tissues, by originating in endemic influences and bad food, insensibly and slowly, and by their very prolonged duration and hopeless cure.

85. Genus i. — Lepra Tuberculosa — Leprosy — *Leprosy of the middle ages* — *Lepra Hebræorum.* — Dusky-red or livid tubercles, of various sizes, on the face, ears, and extremities; a rugous and thickened state of the skin, impaired sensibility and falling out of the hair, excepting on the scalp; hoarse or altered voice, and ozœna; terminating in ulcerations of the affected surface, and extreme fœtor; the distemper being often hereditary, and even contagious by means of the matter discharged from the sores. — *Spec.:* 1st. *Lepra Taurica* — the Leprosy of the Crimea; — 2d. *L. anæsthesiaca;* — 3d. *L. Hebræorum* — Jewish or Egyptian Leprosy. (*See art.* Leprosy.)

86. Genus ii. — Radesyge. — Lassitude, torpor, and heaviness of the limbs, stiffness and pains of the joints; a pale, bloated, leaden, or reddish appearance of the face, hoarseness of the voice, ozæna; a rugous, scaly, and callous state of the skin, especially in parts, followed by cracks, furrows, tuberculous callosities, and ulcers. — *Spec.:* 1st. *R. vulgaris;* — 2d. *R. scorbutica.*

---

* The several forms and states of complication manifested by *Erysipelas* are fully described, in the article referred to, as they have been observed in many countries and climates by the author, and during different epidemic constitutions.

† This malignant and contaminating distemper is generated in horses from crowding, and from breathing a contaminated or foul air, and is communicated from them to man. There is great reason to believe, that most, if not all the maladies comprised under this order, have originated in some of the lower animals, and have extended, with various modifications, to man; and not improbably small-pox has had a similar origin as well as scarlet fever, as already mentioned.

87. GENUS iii. — ELEPHANTIA — *Elephantiasis of the Arabians.* — Hardness, lividity, and great tumefaction of one or both limbs, or of the scrotum, owing to great thickening of the cutaneous and subcutaneous tissues, with an irregular, glabrous, or scaly state of the surface; endemic chiefly in warm countries. — *Spec.:* 1st. *E. vulgaris*; — 2d. *E. tuberosa*; — 3d. *E. Scrotatis.* (*See art.* ELEPHANTIASIS.)

88. GENUS iv. — PELLAGRA. — An endemic and hereditary malady, characterised by thickening, scaly excoriation, cracks, and deep fissures of those parts of the skin exposed to the sun or air; attended by general cachexia, by burning pains in the trunk and limbs, by disorder of the digestive organs and nervous system; at first appearing after prolonged intervals, afterwards being more continued, and often fatal. — *Spec.:* 1st. *P. Milanensis*; — 2d. *P. Asturiensis.* (*See art.* PELLAGRA.)

89. GENUS v. — ICHTHYOSIS. — Morbid enlargement of the papillæ of the skin, and thickening of lamellæ of the epidermis, either in parts, or more or less generally, presenting irregular compartments often resembling the scales of fish. — *Spec.:* 1st. *I. hereditaris*; — 2d. *T. papillaris*; — 3d. *I. localis.* (*See art.* ICHTHYOSIS.)

90. ORDER IX. — CANCRODES — *Cancerous Distempers.* — Cancerous diseases of the skin are characterised by their slow and insidious attack; by their prolonged duration; by their foul ulceration and lancinating pains; by their resistance to treatment, and by their general return to adjoining or remote parts, after removal by excision: they depend on a peculiar diathesis, which is often hereditary.

91. GENUS i. — LUPUS — *Cancer Lupus*, Sauvages. — A disease of all the tissues of a portion of the skin, chiefly of the face, implicating also the subjacent cellular substance; of remarkably slow progress and long duration; always extending either superficially or in depth, with a stinging sensation of heat; passing into ichorous and slow phagedenic ulceration, and destroying the textures to which it extends. — *Spec.:* 1st. *L. superficialis*; — 2d. *L. phagedænicus*; — 3d. *L. non-exedens serpiginosus.* (The different species of Lupus form the connecting links between the *leprous* and the *cancerous* diseases of the skin. *See art.* LUPUS.)

92. GENUS ii. — CARCINUS. — An alteration of all the tissues of the skin and subjacent cellular tissue, generally commencing as a small, hard, indolent tumour, with itching or stinging; passing into pungent or lancinating pains, and often attended or followed by ichorous and slow ulceration, and by general contamination of the frame. — *Spec.:* 1st. *C. scirrhosus*, — *Carcinoma*; — 2d. *C. verrucosus* (Chimney-Sweeps' Cancer): — 3d. *C. medullaris*; — 4th. *C. melanæus*; — 5th. *C. eburnæus.* (*See arts.* CANCER and SCIRRHOUS AND OTHER TUMOURS.)

93. GENUS iii. — KELIS. — A prominent, hard excrescence, sometimes cylindrical, sometimes round or square, flattened in the centre and elevated at the margin, projecting roots into the skin. — *Spec.:* 1st. *R. genuina*; — 2d. *R. spuria.*

94. ORDER X. — HETEROMORPHÆA. — Alterations of the skin, cuticle, or nails, not comprised under the foregoing, nor referable to changes or morbid actions similar to, or allied with, those which characterise the preceding groups.

95. GENUS i. — NÆVUS — *Vascular Nævi — Moles.* — A congenital alteration of a portion of the skin, consisting either of a convoluted congeries of capillary vessels, more or less elevated, in the form of a small vascular tumour, above the surface, or of a more diffused and dark or livid-coloured patch, or of a warty, hairy, or discoloured elevation or excrescence. — *Spec.:* 1st. *N. vascularis circumscriptus*; — 2d. *N. vascularis diffusus*; — 3d. *N. non-vascularis*; — 4th. *N. pilosus.*

96. GENUS ii. — VERRUCA — *Warts.* — A very circumscribed, hard, excrescence, sessile or pedunculated, sometimes moveable, sometimes more fixed, of nearly the same colour as the skin, its surface being rugged, horny, or hard, and not susceptible of inflammation, although the cutaneous papillæ to which it is attached is more than usually vascular. — *Spec.:* 1st. *V. vulgaris*; — 2d. *V. Acrochordon.*

97. GENUS iii. — TYLOSIS — *Corns* — Circumscribed, dry, hard, lamellated callosities, owing to hypertrophy of the cuticle from pressure, which drives the altered structure inwards upon the subjacent tissues, developed chiefly on the toes. — *Spec.:* 1st. *T. indurata*; — 2d. *T. gomphosa*; — 3d. *T. bulbosa.*

98. GENUS iv. — ONYGOSIS. — Inflammation with swelling, redness, and pain of the matrix of the nail, causing malformation, induration, eversion, or inversion of the nail. — *Spec.:* 1st. *O. acuta*; — 2d. *O. chronica*; — 3d. *O. cum Inversione*; — 4th. *O. cum Eversione*; — 5th. *O. complicata vel associata.* (Often associated with *Psoriasis* and *Lepriasis*, which see § 23.)

99. Having exhibited what may be considered a strictly *natural grouping* or *classification* of the changes, appearing either primarily in the tissues of the skin, or contemporaneously with, or consecutively upon, febrile and constitutional diseases, it will be seen that the local connections, the symptomatic relations, and the more prominent features and alliances of these changes, are brought more completely and more accurately under view. And it will be more clearly perceived, that these affections of the skin, so difficult to arrange, and so generally considered and treated as local alterations merely, are more or less important manifestations, in the cutaneous tissues, of disordered or diseased conditions of one or more of the vital functions, — of the organic nervous influence or energy, of the digestive and assimilating functions, of the depurating or eliminating functions, and, consequently, of the circulating fluids, and of the constitution or frame in general. Thus, a natural arrangement of cutaneous affections directs the attention more entirely to the relations, and constitutional and visceral dependencies, of these affections, and leads to rational and successful methods of cure; most of the affections grouped under the same order manifesting such morbid relations and connections, as require similar indications and means for each.

100. As *artificial arrangements of cutaneous diseases* have been so commonly received, and as they tend to facilitate diagnosis, I shall conclude this subject by giving the improved modification of the classification of WILLAN, by M. RAYER; the arrangement of WILLAN being itself only a modification of that originally published by PLENCK.

TABLE.

- **DIVISION I.** Diseases of the Skin.
  - **Chapter I.** Inflammatory Affections, distributed according to the Number and Form of their elementary Lesions.
    - **Section I.** Having a single elementary Form.
      - 1. EXANTHEMATA.—Erythema, Erysipelas, Rubeola, Roseola, Scarlatina, Urticaria; Artificial Exanthemata.
      - 2. BULLÆ. — Pemphigus, Rupia; Artificial Bullæ — Blisters, Ampullæ.
      - 3. VESICULÆ. — Herpes, Eczema, Hydrargyria, Scabies, Miliaris sudatoria (*suette miliaire*), Sudamina; Artificial Vesicles.
      - 4. PUSTULÆ. — Variola, Varicella, Vaccinia, Vaccinella, Acne, Rosacea, Sycosis, Impetigo, Favus, Ecthyma; Artificial Pustules.
      - 5. FURUNCULI. — Hordeolum, Furunculus, Anthrax.
      - 6. GANGRENÆ. — Anthracion vel Pustula maligna, Anthrax Pestis.
      - 7. PAPULÆ. — Strophulus, Lichen, Prurigo; Artificial Papulæ.
      - 8. SQUAMÆ. — Pityriasis, Psoriasis, Lepra, Pellagra; Artificial Squamæ.
      - 9. TUBERCULA. — Lupus, Scrofula, Cancer; Elephantiasis Græcorum; Artificial Tubercles.
    - **Section II.** Having several elementary Forms.
      - 1. SYPHILIS. — Exanthematica, Bullosa, Vesiculosa, Pustulosa, Squamosa, Papulosa, Tuberculosa, Vegetativa.
      - 2. AMBUSTIO. — Exanthematica, Bullosa, Gangrenosa.
      - 3. PERNIO. — Exanthematica, Bullosa, Gangrenosa.
  - **Chapter II.** Peculiar States of the Skin not referable to Inflammation.
    - ANEMIÆ.
    - CONGESTUS SANGUINEI.
    - HÆMORRHAGIÆ. — Purpura (Petechiæ, Vibices, Ecchymoses, Dermatorrhagia).
  - **Chapter III.** Morbid States of the secreting Functions of the Skin.
    - PERSPIRATIONIS Ephidrosis.
    - EPIDERMIDIS Exfoliatio.
  - **Chapter IV.** Neuroses of the Skin.
    - Anæsthesia, Hyperæsthesia.
  - **Chapter V.** Faulty Structure, or unusual States of one or other of the Elements of the Skin.
    - PIGMENTI (Achromata; Dyschromata). — Albinismus seu Leucopathia, Nigrities, Ephelis, Lentigo, Chloasma, Melasma, Nævus pigmentarius, Color cæruleus, Color subflavus; Artificial Discolorations.
    - HYPERTROPHIÆ. GANGRÆNA SIMPLEX. CICATRICES. DEFECTUS CONGENITUS CUTIS. EXTENSIO VEL RELAXATIO INSOLITA CUTIS.
      - Papillarum et Epidermidis. — Ichthyosis, Verruca, Producta cornea, Tylosis.
      - Vasorum Cutis. — Phlebectasia, Angiectasia capillaris, Nævus araneus flammeus, &c. Tumor vascularis.
      - Corii, Membranæ cellularis subcutaneæ, et Telæ adiposæ. — Cheloidea, Tumores varii, Elephantiasis Arabica, Andrum, et Pedarthoræ, Barbadoes Leg, &c.
  - **Chapter VI.** Degenerations.
    - DEGENERATIONES FIBROSÆ.
    - MELANOSIS.
    - DEGENERATIONES TUBERCULOSÆ.
- **DIVISION II.** Alterations of the Dependencies of the Skin.
  - **Chapter I.** Special Diseases of the Sebaceous Follicles.
    - Secretio aucta, Vermes sebacei, Levatio follicularis, Tumor follicularis, Calculi Folliculorum.
  - **Chapter II.** Special Diseases of the Piliferous Follicles.
    - Atrophia, Defectus congenitus Pilorum, Pili supernumerarii; Incrementum insolitum Pilorum, Coactio Pilorum, Alopecia, Canities, Plica.
  - **Chapter III.** Special Diseases of the Ungual Matrices and Alterations of the Nails.
    - Onychia, Vicia Confirmationis et Structuræ Unguium; Ecchymosis subunguialis; Incrementum insolitum Unguium; Situs insolitus; Ficus; Defædatio, Degeneratio; Productio et Reproductio, &c.
- **DIVISION III.** Foreign Bodies on the Surface, under, or in the Substance of the Skin.
  - Parasitic Insects infecting the Skin of Man.
    - Pediculi; Pulices; Acarus Scabiei; Filiaria medinensis; Œstrus.

101. I may further add the arrangement proposed by Professor J. H. BENNETT, of Edinburgh. He excludes from the orders *Exanthemata* and *Pustulæ* the diseases characterised by excessive fever, as being essentially febrile. From the order *Vesiculæ* he also removes miliaria and varicella, for a similar reason; and he expunges the order *Bullæ* altogether. With some other alterations, consisting chiefly of reductions of genera to the rank of species, he assigns the following as his classification of skin-affections. It will be seen that it is a modification, with several omissions, of the arrangement generally adopted *of diseases of the skin*; whilst in that which I have given above, I have comprised also the principal of those maladies which generally also *affect or implicate the skin* in a more or less obvious manner:—

ORDER i. *Exanthemata.*
  Erythema.
  Roseola.
  Urticaria.
ORD. ii. *Vesiculæ.*
  Eczema.
  Herpes.
  Scabies.
  Pemphigus.
ORD. iii. *Pustulæ.*
  Impetigo.
  Ecthyma.
  Acne.
  Rupia.
ORD. iv. *Papulæ.*
  Lichen.
  Prurigo.
ORD. v. *Squamæ.*
  Psoriasis.
  Pityriasis.
  Icthyosis.
ORD. vi. *Tuberculæ.*
  Lepra tuberculosa.
  Lupus.
  Molluscum.
ORD. vii. *Maculæ.*
  Lentigo.
  Ephelides.
  Nævi.
  Purpura.
ORD. viii. *Dermatozoa.*
  Entozoon folliculorum.
  Acarus.
  Pediculus.
ORD. ix. *Dermatophytæ.*
  Porrigophyte (Favus).
  Mentagraphyte (Mentagra).

SLEEP AND SLEEPLESSNESS. — Classif.: — General Pathology—Symptomatology — Therapeutics.

1. Definit. — i. Sleep. — *The suspension of sensation and voluntary motion, occurring at periodic intervals, continuing for some hours, then terminating spontaneously, or by some irritation or excitement, being indispensable to the due discharge of all the sensory, intellectual, and voluntary functions.*

ii. Sleeplessness. — *The non-recurrence of this periodic suspension of sensation and voluntary motion, or the imperfect or interrupted recurrence of it, as a symptom of disease, or as the chief manifestation of disease.*

2. I. Sleep is necessary to the due discharge of the sensory, intellectual, and voluntary functions, for any considerable period; and if that period be much prolonged beyond eighteen or twenty hours, even during states of excitement or anxiety, an overpowering disposition to sleep is experienced; although powerful constitutions, on trying occasions, may continue awake for much longer periods. The organic functions, or those functions which are actuated by the organic, nervous, or ganglial system, and which consist chiefly of digestion, assimilation, circulation, nutrition, and secretion — all these functions, commonly termed involuntary—require not the suspension or repose constituting sleep, which, if extended to them, would soon terminate life. But these functions are performed — at least, some of them —with less activity during this period. Sleep is not only indispensably requisite to the adequate discharge of the functions performed by the cerebro-spinal nervous system, but is also necessary to the due nutrition of this system — to the due supply of the waste of nervous power, and even of intimate nervous organisation, required for the healthy performance of the functions of this system. Whilst the ganglial nervous system, on the one hand, discharges its functions through the media of the several organs actuated by it almost continuously, and without marked repose or waste of substance or structure, the cerebro-spinal nervous system, on the other hand, demands periodic or alternate repose and action, in order to insure its healthy function and organisation, and to prevent excessive exhaustion and waste.

3. The restoration of cerebro-spinal nervous power consequent upon sleep has been, by some physiologists, attributed to the due nutrition of the cerebro-spinal organs during this period, as much as to the suspension of exhaustion and waste, this restoration and nutrition being requisite in proportion to the antecedent waste, which, if not duly restored, successively increases until the intimate organisation of these nervous centres ultimately undergoes irreparable and tangible change. In early age and during manhood, the voluntary actions and mental exertion may be continued during comparatively long periods without exhaustion, for nutrition, or the restoration of the nervous expenditure, is then more rapid and complete than in advanced or old age; whereas, at this age, these efforts, especially such as are of a very exhausting nature, are followed by a more prolonged and a more urgent want of repose; and if repose be not obtained, disease, or even disorganisation, more especially inflammation, in the earlier epochs of life, and apoplexy and paralysis in advanced age, may speedily supervene. Thus we observe that when, in advanced life, mental exertion, bodily fatigue, or venereal indulgences are carried too far, the disposition to sleep is most urgent, and, if the required repose be not obtained, the risk from the supervention of these maladies becomes great.

4. The seat of consciousness, or of active sensation, has been long since supposed by some writers to be different from that of the mental faculties; and it has been believed that, whilst the former is in the central and basilar parts of the brain, the latter are to be referred to the convolutions of the hemispheres. During sleep, therefore, the more central parts, the seats of sensation, are altogether inactive, or incapable of feeling or perceiving impressions made upon the senses, and thence conveyed to those parts, unless the impressions be so strong as to rouse them to a state of activity: but whilst sleep consists of the inaction or repose of these parts, and of the hemispheric convolutions as well, when sleep is complete or profound, a less profound form of sleep consists of a less complete state of inaction of both the hemispheric convolutions and the central cerebral structures. This latter, or imperfect state of sleep comprises numerous phases or grades from that attended by indistinct *dreams*, through the various states of *dreaming*, until the half-waking and half-sleeping state is reached.

5. During *dreaming*, the structures of the brain more especially concerned in the mental manifestations are not completely or entirely in a state of repose, nor can it be admitted, that the seats of conscious sensation are also completely or profoundly inactive, otherwise the former manifestations could not be perceived or remembered by the latter. It will be, therefore,

more correct to view the several portions of the brain concerned in sensation, mental manifestation and volition, as not completely, although more or less, inactive during sleep, unless the sleep be very deep, and altogether without dreams; for, more frequently, especially when the dreams are distinct, and are recollected upon awakening from sleep, certain parts of the brain continue more or less active, repose not being universal and complete. Dreaming during sleep in health may be rendered more vivid and remarkable by the excitement of the brain during the various mental or physical exertions of the day, or by the nature of the food or drink, or by disorders of the digestive functions, the imagination and reasoning powers being either partially or actively exercised, and the results of these being remembered when waking. This partial or irregular activity of the hemispheric portions of the brain during sleep is often still more strongly manifested during the imperfect sleep of fever, and is even expressed more or less audibly and actively; those suggestions, conceptions, and unconnected ideas, constituting dreams in health, passing into more or less manifest delirium in states of disease. Thus various grades of sleep and of dreaming may exist either occasionally or habitually during the ordinary health of the individual; and thus, during disease, various grades or phases of delirium, passing into sopor, lethargy, and coma, may occur, as the states of nervous power and of the circulation may favour their appearance.

6. During sleep, especially when it is not profound, the sensorium may be influenced in various ways, so as to give rise to changes of position, to various conceptions, and even to acts, without a conscious perception of them. An uneasy position, or the muscular sense, may occasion during sleep a complete change of position, — a person may turn from one side to the other, without being conscious of either the cause or the act of turning. In this case, the uneasiness influences the sensorium, or induces an unconscious sensation sufficient to give rise to a similarly unconscious volition productive of the act, but there is no perception of it. During dreaming, the conception of numerous occurrences, circumstances, and acts, passes through the mind with greater or less rapidity, and generally in a very incongruous and unconnected manner. The various processes of thought which had engaged the waking brain are often partially renewed or suggested during sleep, or while the mind is unconscious of impressions on the senses, frequently in singular forms, or with inconceivable rapidity, or in disjointed or impossible states; these suggestions or conceptions being, however, sufficiently strong, in many cases, to excite conscious sensation, so far, at least, as to be partially remembered on waking.

7. These suggestions seldom amount to perfect conceptions, but are loose and unconnected, generally faintly entertained, and soon extinguished. They are the results of imperfect or disordered states of repose of the parts of the brain more especially concerned in the mental processes. They may occur without any excitement or stimulus of the senses, or of parts distant from the brain, as apparitions merely of anterior processes of thought or of acts, in partial or newly-combined and bizarre forms, without any circumstance which can account for their appearance; and they may assume the most lively characters, and be attended by more or less correct reasoning, and by the highest flights of imagination. But in some instances, they may be referred, with great accuracy, to antecedent occurrences, occupations, or mental processes, of which they are the imperfect or distorted remains or apparitions, although sometimes the most lively or intense, but also the most incongruous conceptions. In other cases they are excited by local impressions, or irritants, or changes which sympathetically affect the brain, so as to give rise to those conceptions which constitute dreams, or even to acts, which those conceptions occasion. Thus the irritation of the bladder may give rise, during sleep, to conceptions connected with micturition, and this act may even follow without waking, although it generally immediately terminates the sleep. Thus, also, irritation of the vesiculæ seminales produces lascivious dreams, and not infrequently is followed by seminal emission. Various internal excitants, moreover, or external agents, acting during sleep, may be followed by dreams having a more or less obvious connection with the causes which produced them; the impressions made by such agents calling up certain related, although incongruous or disjointed conceptions in the sensorium.

8. The conceptions arising in the manner now explained, — either with or without any obvious excitant or physical cause, — may be so slight and evanescent as hardly to be remembered upon awaking, and as not to occasion any change of position, or any act implying volition, of either a conscious or unconscious kind. But not infrequently the conceptions formed during sleep, when lively or active, give rise to volition, and are followed by acts. The individual acts the dream, or performs the conception passing through his mind, without being so conscious of his act as to remember it when he awakes, or when the functions of sense and perception are fully restored. This constitutes *somnambulism*, or sleep-walking, a state of partial or imperfect sleep, which has been sufficiently noticed, in respect of its nature and relations, when treating of *the pathology of* Paralysis (see § 193. *et seq.*).

9. *Sleep*, that it may be refreshing and restorative to both body and mind, should, 1st., take place at a stated and proper hour, and after stated intervals; — 2d., continue for a certain period of time, without being prolonged much beyond that time; — 3d., be aided by the necessary preparations to secure ease of position, and to prevent disturbance of the vital and animal functions. When sleep is obtained without these precautions, — when it occurs at unseasonable hours, — when it is broken or unusually shortened, — when it is taken on a loaded stomach, or after the ingurgitation of heating or stimulating beverages, — when the position of the body is unusual, cramped, or uneasy, — when the stomach or bowels are distended by flatulence, or irritated by acidity, — then it is either disturbed or unsound, unrefreshing, — the body and mind are left on waking either languid or torpid, and the requisite exertions or engagements of the following day are entered upon with disrelish, and are soon productive of fatigue.

10. To secure refreshing sleep, a sufficiently early and a punctual period of retiring to repose should be adopted, after having spent a reasonable period in the open air, chiefly in exercise suited to

the state and constitution of the individual. The diet should be digestible and moderate in quantity, and such as will not favour flatulency or acidity. Repose ought not be taken for some hours after a full meal; and the place in which it should be sought ought to be airy and dry, the temperature being not above 70° of Fahr. or below 55°. The bed should be firm and moderately elastic, slightly elevated towards the head, and the clothes, both above and under the person, sufficiently warm and light. All the day-clothes should be taken off. The chamber ought to be large and airy, and light and noise excluded. If air be not sufficiently renewed in the sleeping apartment, sleep becomes feverish or restless, and the individual awakes unrefreshed and uncomfortable.

11. The *amount* of sleep should vary with the age, the occupation, the constitution, and the habits of the individual. During infancy and childhood, prolonged periods of sleep are required for the nutrition of the nervous masses and the growth of the body. Infants sleep the greater part of the twenty-four hours. Children require twelve or fourteen hours; older children, or those from eight years until fourteen or fifteen, about ten hours. From commencing puberty until full growth, or from twenty-five to thirty, eight hours are sufficient. After this age, the duration of sleep should range from six to eight hours, according to the occupations or exertions, mental or physical, of the individual.

12. *The causes of sleep* are not only the fatigue, the exhaustion, and the periodicity characterising all our sensorial actions and manifestations already insisted upon as requiring restoration and reinforcement of nervous power during the periods of repose, but also various states and phenomena which act more or less on the sensorium of those who are either incapable, or not in a situation, of having recourse to those mental or physical operations which more certainly conduce to repose. The entire *absence* of sensorial impressions, or the *monotonous repetition* of such impressions, will frequently occasion sleep, as occurs when listening to a drawling, monotonous reader or preacher, or to distant sounds of unvarying loudness. Persons who have become accustomed to sleep, notwithstanding the continuance of sounds which would keep the unaccustomed awake, frequently cannot sleep when deprived of these sounds, or when removed to perfect stillness, or when they are within the reach of sounds of a different intensity or key. Friction of various parts, especially in nervous or susceptible persons, prolonged combing of the hair, monotonous sounds of any kind, continued and gentle motions of the body in the same directions, rapid transport of the body backwards, or with the back placed towards the place where the body is carried, as when thus seated in a carriage, or on a railway, and directing the mind to uninteresting objects or matters, severally induce sleep, especially when other circumstances concur in causing this effect. There are, moreover, other causes which produce sleep, and which may be viewed as pathological, inasmuch as they are more or less morbid in their consequences or nature: they require merely enumeration. Venereal excesses may occasion sleep, lethargy, or sopor, especially in the aged; extreme exhaustion of the organic nervous and cerebro-spinal energies; a plethoric state of the brain, or of the vascular system generally; the superabundance of excrementitious materials in the blood, or an imperfect oxidation of this fluid; the administration of narcotising substances; and various related morbid affections induce sleep, either excessive as respects its continuance, or of a disordered or unrefreshing kind (see *art.* COMA and LETHARGY).

13. *The accession of sleep* is very different in different persons, or when sleep supervenes naturally and healthily, and when it is induced artificially, or assumes more or less of a disordered character. Healthy sleep may occur either suddenly or gradually. Disordered sleep is generally slow and partial in its accession. The sensorium gradually loses its control over the current of the ideas, which becomes unconnected and incongruous; and in this state of transition, — of half sleeping and half waking, — a dreamy, or even a delirious existence is passed for a longer or shorter period, until an entire loss of sensibility of external objects, — a more complete torpor of the sensorial parts of the brain, — supervenes, and sounder sleep is induced. The disposition to, and indisposition from, sleep are very much in the power of the individual, for, by abstracting the mind from all objects of sense, and from the suggestions or ideas they excite, by ceasing every phase or mode of volition, and by ceasing to think upon or respecting any topic requiring mental exertion, or calculated to occasion mental excitement, or by directing the attention to, and fixing it on, a single, uninteresting, unexciting, or simple object, and engaging the thoughts with no other, the sensorium will soon lapse into that state of torpor productive of sleep.

14. The accession of sleep is often *attended by various morbid phenomena*, especially in persons predisposed or subject to any nervous, or spasmodic, or paralytic affection. These consist chiefly of startings, twitchings, contractions, or cramps, of one or more limbs or muscles; of convulsions and spasmodic laryngeal disorders, or croup, in children; of epileptic fits, more or less complete, or merely slight or partial, and even of various mental and spectral illusions. Any of the foregoing may occur upon the accession of sleep, and before sleep has become complete, or immediately upon falling asleep; or during the commencement of sleep, when sensation is partially or suddenly excited by any excitant, or disturbing cause.

15. *Awakening* from sleep may be either sudden or gradual. The healthy and sufficiently sound and prolonged sleep terminates spontaneously and immediately, leaving the person who has enjoyed it refreshed and active; or if it be terminated by impressions made upon the senses, these impressions produce this effect readily and completely, — an effect not observed from them when the sleep is of that morbid kind which constitutes lethargy, stupor, sopor, or coma, in its several morbid grades. Disordered, unsound, or insufficient sleep generally passes into that state of half sleeping and waking noticed above (§ 4.), and, according to the circumstances causing the disorder or unsoundness, is attended by the dreamy, or even by the delirious states of temporary existence just mentioned, until stronger impressions on the organs of sense, or diminished torpor of the sensorium, — the increased activity of the sensorial or conscious portions of the brain, — are followed by

the restoration of the several manifestations or functions of this organ.

16. *Sleep may be excessive.* — 1st. As respects its duration. — 2d. As regards its profound character, and the difficulty of arousing the person from it; and 3d. In the frequency of its recurrence. These are diseased states, and either amount to one or other of those described under the heads COMA and LETHARGY, or generally pass into one or other of them, if not soon arrested by a treatment appropriate to the exciting and pathological causes which occasion them. Too profound or prolonged sleep should always excite suspicions of a disposition to, or the actual presence of, cerebral congestion, owing either to nervous exhaustion, or to a morbid state of the cerebral circulation, or to an interrupted return of blood from the brain, occasioned by pulmonary or cardiac engorgements, or to a morbid state of the blood itself. To one or other of these morbid conditions, excessive or deep sleep, especially when amounting to lethargy or sopor, may be imputed, the existence of either condition, or of more than one, generally becoming manifest upon a careful examination of the case.

17. II. SLEEPLESSNESS — *Wakefulness* — *'Αγρυπνία*—*Insomnia*—*Pervigilium*— is a symptom of disease, but it sometimes is also a forerunner of the worst forms of disease, or occurs before any very obvious disorder can be recognised. An interrupted sleep, or a more or less incomplete form of wakefulness — states of partial sleeplessness — may occur in consequence of too varied or too anxious states of mental occupation, or of the use of various beverages, or indigestible articles of food, near the period of repose, which prevent the accession of sleep, as green tea, coffee, &c. But when it is not induced by any of these causes, and even when the wakefulness occasioned by them is complete, it should be considered as a most important symptom, and its pathological cause ought to be carefully investigated. *Wakefulness* may be either *partial* or *complete:* the former may be so frequent as to be habitual, or merely occasional; the latter cannot be of long continuance without being followed by dangerous disease.

18. i. *Partial or incomplete sleeplessness* is of frequent occurrence, especially in persons whose minds are much and anxiously engaged, or whose occupations subject them to great mental exertion, or to the vicissitudes of fortune. It may likewise follow the unreasonable indulgence of grief, severe losses of any kind, and the numerous vexations and disappointments of life. When it is continued nightly for a long period, it may superinduce serious disease of the brain, or of the heart, or some other organ, as the cause of the wakefulness may operate upon the frame; the nature of the cause having a more or less special influence upon either the brain, heart, lungs, liver, &c., according to the susceptibility or predisposition of these organs. Partial insomnia is often occasioned by sleeping with too many clothes on the bed, or by the use of curtains to the bed, and to the closeness with which they are drawn, or by an insufficient renewal of the air in the sleeping-chamber. These causes, especially the breathing of an impure or self-contaminated air, induces a febrile state, attended by headache, restlessness, and more or less complete pervigilium, the tongue and mouth being foul and clammy in the morning, and the person unrefreshed, or even much more fatigued and disordered than when repose was sought.

19. Partial sleeplessness has always a most intimate relation to the states of morbid action, and, according to these states, is attended by peculiar features. The sleeplessness may be occasioned, or the sleep may be broken, interrupted, or unsound, by indigestion, flatulence, or acidity of the stomach or bowels, or it may be disturbed by cramps or spasms of various muscles. This association is often observed in gouty and dyspeptic persons: the irritation of the prima via by flatus, acidity, or undigested articles, disorders the ganglionic nerves, and, through the medium of them, disturbs the sleep, excites the brain and spinal chord, the irritation thus extended to these centres being, in some cases, reflected from them to one or more of the muscles of voluntary motion, occasioning spasm or cramp. When wakefulness proceeds from the disordered digestion consequent upon indigestible articles of food, or upon an overloaded stomach, there is not merely more or less restlessness, but also often a feeling of oppression, a disposition to sleep, which, when it takes place, is generally attended by disturbing or fearful dreams, or by the nightmare, the individual waking up in fright, with a dry mouth and excited pulse.

20. When this state of sleeplessness is occasioned by mental exertion, or by continued mental rumination, when retiring to rest, on the subjects which have just before engaged the mind, whether these subjects be abstract or emotional, — whether they be intricate or difficult in their nature, or calculated to perpetuate anxiety or distress, — then feverishness, headache, restlessness, thirst, &c., are apt to occur, and to render sleep, when it at last takes place, unquiet, disturbed by dreams, and unrefreshing. In some cases of this kind, more especially, the person often dreams aloud, and, in rare instances, particularly when there is much nervous susceptibility and mental activity, he *acts his dream,* and evinces a more or less complete state of *somnambulism,* or *sleep-walking.* A youth, whom I knew, was much engaged in becoming an accomplished player on the flute; his dreams had frequent reference to this study, and he often disturbed the family by his performances on this instrument during his sleep. I was called one night to a young lady, who had disturbed and alarmed her relations by walking through more than one of her apartments in her night-dress, singing some songs she had been recently practising. And another young lady, whom I saw on this account, sometimes left her chamber in her sleeping-dress, and sat down to the piano in another room and performed some pieces of music which she had been learning. Females, who are somnambulists, generally first evince this disorder either at the period of puberty, previously to, or about, the accession of the catamenia, or where this discharge is interrupted or otherwise deranged.

21. Persons labouring under disease of the substance or valves of the heart, are subject not only to imperfect and disturbed sleep, but also to fearful dreams; and if they fall asleep in an uneasy position, or on the left side, in some cases, they generally waken up soon after from a fearful dream, as falling from a precipice, drowning, &c.; their dreams being more pleasant when the position is more comfortable. The same phenomena

are often observed in dyspeptic subjects, when the stomach or colon is distended by flatus; for, when the individual lies on the left side, the weight of the body presses on it, whilst the liver presses on the stomach and colon, and the flatulent distension of these pushes the diaphragm upon the heart, and embarrasses the circulation through this organ.

22. There are very few chronic diseases of which partial wakefulness is not a symptom; but it is more especially distressing in atonic gout, rheumatism, affections of the skin, and disorders of the urinary organs. Anomalous states of hysteria, the several forms of dyspepsia, and derangements of the functions of digestion, are, as well as the foregoing, attended by partial wakefulness, or by a disturbed, insufficient, and unrefreshing sleep. Certain beverages and articles of diet may be the chief cause; and when these are relinquished, the sleep becomes more sound. Tea, especially green tea, coffee, and spirituous liquors, often occasion wakefulness; and a full meal of animal food, especially of pork, late in the day, often causes either restlessness, loss of sleep, or disturbing dreams. It would be unprofitable, as it is unnecessary, further to notice the contingent occurrence of want of sleep in chronic diseases, as it is very generally observed and readily accounted for.

23. ii. *Complete sleeplessness* is often a most important symptom of disease, and when it occurs without any manifest physical disorder to account for its existence, it should be viewed as the forerunner of dangerous disease, particularly of the brain. Complete wakefulness, even for many nights, is generally attendant upon nervous and other fevers of a continued type, upon inflammations of the brain, and upon inflammatory affections of an acute character. It also attends the eruptive fevers, rheumatic fevers, the gouty paroxysm, painful and spasmodic maladies, and pestilential distempers. When it is continued for many nights and days, vital power and resistance become exhausted, and delirium, followed by coma, is very apt to supervene. All acute diseases attended by febrile excitement or increased vascular action, especially towards or during the night, are characterised by a more or less complete insomnia; and when the febrile action subsides, then sleep returns, the occurrence of sleep often proving critical of these diseases (see *art.* CRISIS).

24. When insomnia is not followed by sound repose after a long continuance, it often passes into a state of half-sleeping and half-waking, in which the ideas of the patient are rapid, unconnected, and otherwise disordered, and generally expressed aloud, or in a low key. He dreams aloud in this half-conscious condition; or becomes more obviously delirious. The slighter forms of this delirium have usually been called wanderings of the mind; and at first they appear only occasionally, or during the night merely; but when they are not soon followed by composed sleep, are apt to be more continued, more fully developed, and to pass ultimately into sopor or coma.

25. If wakefulness is unattended by any very manifest disorder, or even by slight disorder, or such as appears insufficient to account for it, some serious disease of the brain should be viewed as impending, although a considerable time may elapse before the advent of it. In these cases, the symptoms more especially connected with the nervous systems should be carefully investigated, in connection with the occupation, habits, modes of living, arrangements for sleeping, ventilation, &c. The temperature of the head, action of the carotid arteries, the functions of sense, and those of digestion, assimilation and excretion, ought to be carefully examined, and a treatment, based on the report thereby obtained, should be adopted. A dignitary of the church consulted me for prolonged insomnia. He evinced no other disorder. Palsy, or apoplexy, or coma was dreaded, and the treatment was directed accordingly. He was soon very much better, and continued so for two or three years, during which time I did not see him; but at the termination of it he was seized with apoplexy, at a great distance from London, and died in a few hours. An eminent physician and author was afflicted with insomnia, he afterwards became insane. A patient to whom I was called had long been subject to wakefulness, and was afterwards attacked with phrenitis.

26. Pervigilium is not infrequent *in nervous females, after their confinements,* especially when they breathe a close or impure air, or when they have experienced hæmorrhagic or exhausting discharges. It may pass gradually, or even suddenly, into delirium or mania, if not arrested by an appropriate method of cure. I have been called to several cases of this kind, where the disorder was aggravated by a treatment diametrically opposite to what ought to have been adopted, and which, when adopted, speedily cured the patient. This is a most important affection in the puerperal state, and should, even when attended by no other manifest disorder, receive constant attention, and suggest the most decided and appropriate means of cure, — appropriate, however, to the various circumstances which occasion it, to the several associations in which it is presented to us, and to the maladies of which it is either the precursor or the attendant.

27. Insomnia is sometimes met with in *young and even in older children*: in them it should be viewed either as the precursor of serious disease, or as caused by some latent or undeveloped morbid condition. It not infrequently precedes or attends disease of the membranes or substance of the brain, especially tubercular deposits in the former, or softening of the latter, before serous effusions take place to any considerable amount; or it accompanies the earlier and more latent stages of these lesions.

28. iii. *The treatment of insomnia* should be altogether based upon those *indications of cure* which the disease of which insomnia is symptomatic, or of which it is the precursor, should rationally suggest. It is owing chiefly to a neglect of this principle, that means, directed more particularly to this symptom, either fail of producing their intended effects, or even often greatly aggravate this particular disorder. In all cases of insomnia, attention should be directed to the age, temperament, habit of body, modes of life, and diathesis or morbid tendencies of the patient, before measures should be prescribed for the disorder; and these measures ought to be especially devised against the disease on which the wakefulness depends. A principal indication is to remove the several causes, remote, external, physical, and pathological, which occasion it, more particularly

to correct a close or contaminated air; to reduce the temperature of the apartment, when it is high, and the quantity or warmth of the bed-clothes; to remove all the excitants of the senses; to abstract the mind from all exciting, harassing, or engaging thoughts, and to direct it to such as are uninteresting or unexciting — to one simple unimportant topic; and to remove or counteract the morbid conditions, of which this is a symptom or prominent consequence. In both young and aged subjects, but especially in the dyspeptic and gouty, the accumulations of disordered secretions and excretions, — of fæcal or contaminating matters, — of flatus, of acid or saburral materials, — or a loaded state of the stomach or bowels, are apt to take place, and require free evacuation and correction by laxatives, conjoined with antacids and absorbents. The existence of a plethoric state of the vascular system, or of engorgement of the liver and portal system, should suggest a repeated recourse to purgatives, deobstruents, and alkaline preparations.

29. When there is actual fulness of the cerebral vessels, or cerebral congestion, then local vascular depletions, purgatives, derivatives, the shower-bath, warm stimulating pediluvia, &c., should be prescribed; and, if the insomnia appears to be caused by increased vascular action, or by febrile disturbance towards night, or by augmented determination of blood to the brain, antimonial preparations, or other diaphoretics, conjoined with alkalies, &c., will generally procure sleep, whilst narcotics, exhibited in such cases, would only aggravate the disorder, induce headache, and increase disorder of the digestive functions.

30. Anodynes and narcotics should not be exhibited in cases of either incomplete or prolonged wakefulness, until general plethora or local congestions be removed by the means now suggested, — until morbid secretions, excretions, and fæcal accumulations have been completely evacuated. But they are important means after these ends have been attained, and when this disorder occurs in nervous, hysterical, or irritable temperaments; when it follows copious losses of blood, or exhausting discharges, and when it is thus met with in the puerperal state. In these circumstances, the choice of the agent should depend upon the peculiarities of the case, upon the existence or non-existence of anæmia, and upon the evidence as to the purity or richness of the blood, and as to the actions of the several emunctories. When there is anæmia, or great debility or nervous susceptibility, the preparations of opium, or of hop, or of henbane, or of poppy, with those of iron, or the vegetable bitters and the alkaline sub-carbonates, will generally be of service; but all narcotics in such cases should be given two or three hours before the desired period of their operation, more particularly opiates; and in order to secure their effects, and to prevent headache, sickness, or other disorder in the morning, they should be combined with aromatics and alkalies. In some cases, it may be preferable to administer the narcotic in a suitable enema or suppository; or the odour of it may be inhaled during respiration, by lying with the head on a pillow containing a narcotic substance, as hops, &c.

31. When sleep is disturbed by cramps, nightmare, frightful dreams, &c., the bed should be elevated towards the head, and acidity of the prima via and costiveness ought to be prevented by magnesia, either alone or with sulphur, or with an antimonial preparation; and food should not be taken for several hours before retiring to rest. Persons who are subject to partial wakefulness, or to troublesome dreams, or to sleep-walking, should be submitted to the curative means now advised, adapting these, however, to the peculiarities of each case. Due exercise in the open air, attention to the digestive functions, and a common-sense regulation of the moral manifestations and physical powers, will generally aid the effects of appropriate medical treatment. In all cases, the use of substances or beverages which are liable to disturb the digestive functions, to occasion heartburn or flatulence, or to excite the nervous system, more especially during the advanced hours of the afternoon or evening, the reading of exciting writings late in the evening, and reading in bed, more particularly, should be avoided; and, if wakefulness or disturbed sleep occur in persons who are addicted to these practices, it should, in great measure at least, be attributed to them, and the relinquishment of them ought to be insisted on.

CLASSIF.: — 1st. CLASS, Febrile Diseases; 3d. *Order*, Eruptive Fevers (*Cullen*). — 3d. CLASS, Diseases of the Sanguineous Function; 3d. *Order*, Eruptive Fevers (*Good*). — III. CLASS. III. ORDER (*Author, in Preface*).

1. DEFINIT. — *Small-pox is the product, and is productive, of a morbid poison or miasm, which, after a period, developes fever, followed by an eruption on the surface of the body, passing through the stages of pimple, vesicle, pustule, and scab, with other concomitant or succeeding affections; the disease running a determinate course, leaving marks in the seats of eruption, and removing from the constitution the susceptibility of another attack.*

2. I. Historical Sketch. — The term *variola* is probably of monkish origin, it being the diminutive of *varus*, a pimple. The term *pock* is of Saxon origin, and signifies a bag or pouch. The epithets *petite* in France, and *small* in England, were added soon after the appearance of syphilis, or the grand or great pox, in Europe, in 1498. In Scotland the word pox is still used without the prefix.

3. Dr. Hahn endeavoured to prove, early in the last century, that the Greeks and Romans were acquainted with small-pox; and, much more recently, Dr. Willan and Dr. Baron have followed in the same track. Rhazes, who was the first accurately to describe this malady, was also the first to refer to the writings of Galen, in proof of its having been known to the Greeks; but, as Dr. Greenhill has shown in his able notes to his admirable translation of Rhazes, the ἴονθος of Galen was not small-pox, but the *acne* of modern authors. Mr. Moore has striven to show that small-pox was known in China and Hindostan, even before the time of Hippocrates. Dr. Gregory remarks, that he is incredulous of this having been the fact, and that he "is borne out in this scepticism by the opinions of Dr. Friend, Dr. Mead, and many other physicians of great learning, and equally indefatigable in research." It is not, however, improbable, that the disease may have appeared or prevailed in China and other adjoining countries very long before it was known in Arabia or Syria, and that it may have taken even a much longer period to have extended from the former to the latter countries than it took to reach the western parts of Europe.

4. That small-pox was not known to either Greek or Arabian writers early in the 6th century, is manifest from the circumstance of no mention having been made of it in the work of Alexander Trallianus, in which all the diseases then known are briefly described. Dr. Gregory, in his very excellent work on "Eruptive Fevers," remarks, that "the first notice of a disease which looks like small-pox, is to be found in a chapter of Procopius, 'De Bello Persico' (lib. ii. c. 22.), where he describes a dreadful pestilence which began at Pelusium in Egypt, about the year 544." But I cannot agree with this view; for Procopius states that malady to have been attended by buboes and carbuncles, which, with the other particulars mentioned by him, point rather to the plague than to small-pox. Dr. Gregory, however, adds, that whether this "disease was small-pox or not may be doubted; but certainly within a short time afterwards very unequivocal traces of small-pox are to be met with in the countries bordering on the Red Sea, for we read of caliphs and caliph's daughters being pitted." (*Op. Cit.*, p. 35.)

5. It cannot be doubted that small-pox had prevailed and been well known in Arabian and adjoining countries, and even in the western parts of Europe, some centuries before Rhazes described it at the commencement of the 10th century; and probably it was even much earlier known in China, or in some eastern countries, than in these. Mr. Bruce, the celebrated traveller, believed that the first epidemic of small-pox of which any notice can be found, occurred in 522. Mead says that, according to an Arabian manuscript, in the library of Leyden, this malady appeared for the first time in 572, the year of the birth of Mahomet, in Arabia, where it was introduced by an Abyssinian army. Marius, bishop of Avenches, remarks in the second volume of his "*Historia Francorum Scriptorum*," &c., that it existed in Europe two years before this date, and that it ravaged France and Italy. Marius, who sat in the second council of Maçon, held in 585, states positively, in his chronicle, that in 570, "*morbus validus cum profluvio ventris et variolis, Italiam Galliamque valde afflixit;*" that it ceased for some years, and reappeared in 580 in the same form as in 570. He adds, that Dagobert and Clodobert, sons of king Chilperic and Fredegonda, died of this malady; that the wife of Gontran, king of Burgundy, was also attacked in 580, and that, feeling her dissolution near, she accused her two physicians, Nicolas and Donat, of having poisoned her, and requested their execution, which was carried into effect over her tomb.

6. M. Monfalcon states, that Ahron, a physician of Alexandria, at the commencement of the 7th century, first mentioned the symptoms, the different varieties, and the treatment of small-pox; and that, in 640, during the reign of the caliph Omar, when the irruption of the Arabs or Saracens into Egypt took place, the disease appeared in so destructive a manner, as to lead many contemporary writers to suppose that it was a new pestilence. It appears to have extended during the 7th century to all the countries whither the Saracenic conquerors carried their arms.

7. Although Rhazes was the first to write expressly and fully on small-pox, he does not pretend to have been the first who had noticed it, for he gives extracts from the works of Ahron, the elder Mesue, and the elder Serapion, in which mention is made of it. This malady was afterwards noticed by Avicenna, Hali-Abbas, and other Arabian authors. It appears to have reached England towards the close of the 9th century, or even earlier. After or during the Crusades, the spread of the malady appeared more extended. It then prevailed in most of the temperate countries of Europe. Bernard Gordon, professor of medicine at Montpellier, in 1285, notices the frequency and fatality of the disease in France at that time; but it does not appear to have been so early known in Norway, Lapland, and other very northern countries; the coldness and dryness of the air probably retarding its progress to them. Dr. Gregory states that the word Variola is to be found in several Latin manuscripts in the British Museum of dates decidedly prior to 900. It should not be overlooked that the contagious nature of small-pox was admitted by all the Arabian and other early writers.

8. From Europe, small-pox was carried across the Atlantic to Mexico, which it devastated in 1527, and spread from thence, with fearful virulence, throughout the American continent. The ravages of small-pox were especially great within the tropics, and still are most remarkably so in the dark-skinned races, as sufficiently demonstrated to my own observation. From the earliest notices of the malady, until the appearance of the writings of Sydenham, there is little to mention in the history of its progress, prevalences, or treatment, further than that it was the most generally diffused, the most frequently epidemic, the most fatal, and the worst treated, of all known pesti-

lences. The heating or sweating regimen had gradually reached its acme when SYDENHAM appeared. He not only accurately described this disease, but distinguished it from measles, and reformed the treatment of it. BOERHAAVE and VAN SWIETEN adopted and carried out the views of SYDENHAM, and demonstrated the extension of the malady by means of a specific miasm or virus alone.

9. The *inoculation*, or artificial production, of the disease was then only brought into notice in Europe, although it had been practised in various countries for ages previously. We have no information as to the period when this resource was first adopted, or as to the circumstances which suggested it. It is by no means improbable, that the well-known contagious nature of small-pox, the greater severity of the disease in childhood and infancy than in adult age, the admitted liability of all to be infected, the immunity from a second attack, and the desire generally felt of having what was inevitable undergone as early in life as possible, may have suggested to those exercising the healing art the experiment of artificially communicating the disease, when prevailing in a mild form, to children and those exposed to its infection, in order to secure an immunity from it in after-life; and it is equally probable that those considerations influenced many in more countries than one, and at different eras. The obvious advantages which resulted must have led to the diffusion and the continuance of the practice. VOLTAIRE, writing as early as 1727 in favour of inoculation, remarks, that the females of Circassia and Georgia were, from times immemorial, in the habit of communicating the small-pox to their children at as early an age as six months, by making an incision in the arm, and by inserting in this incision the contents of a pustule taken from another child. M. MONFALCON states, that inoculation was practised from remote antiquity in Africa, especially on the coasts of Barbary, in China, Hindostan, Egypt, Armenia, Tartary, in Greece, and even in Wales and some parts of the west of England, and in Auvergne and Perigord in France. He does not, however, give the authorities for this statement. BARTHOLIN, who wrote about the middle of the 17th century, states that inoculation had been long used in some parts of Denmark. MONFALCON remarks, that it was employed for the first time in Constantinople in 1673, and BRUCE, the celebrated traveller, says that it had been practised for ages in Nubia. Dr. E. TIMONI, Mr. KENNEDY, and Dr. PYLARINI, in 1714 and 1715, made the profession in England acquainted with it, but no attention was paid to it, until Lady MARY WORTLEY MONTAGUE had her son inoculated at Constantinople in 1717, and her daughter in 1721 in England. After successful trials upon six condemned criminals in Newgate, the Princess of Wales submitted successfully her own daughters to the new process in 1722. VOLTAIRE, in 1727, was the first writer in France to direct popular opinion in favour of inoculation. His observations on the subject may even now be read with interest. He remarks, that most of the 20,000 who died of small-pox in Paris in 1720, would have been saved if inoculation had been then introduced.

10. The first ten years of the career of inoculation in this country, Dr. GREGORY observes, were singularly unfortunate. It fell into bad hands; it was tried on the worst possible subjects, and practised in the most injudicious manner. The consequence was that it soon fell into disrepute. The pulpit, too, sounded the alarm; and conducted as inoculation then was, it was a questionable improvement. A new era in this practice arose in 1746. The Small-pox Hospital was founded for the extension of inoculation among the poor. In 1754, the College of Physicians put forth a strong recommendation of the practice, and MEAD and DE LA CONDAMINE wrote treatises in favour of it. In 1763, the practice was especially adopted by Mr. R. SUTTON and his two sons, who inoculated with great skill and success. "In 1775, a dispensary was opened in London for the gratuitous inoculation of the poor at their own houses; but the institution failed, chiefly through the opposition of Mr. DIMSDALE, who had succeeded the SUTTONS, and fully equalled them in popularity and success. The Small-pox Hospital then took up the plan of promiscuous inoculation, which was carried on, to an immense extent, between the years 1790 and 1800. In 1798, Dr. JENNER announced the discovery of vaccination. In May, 1808, the inoculation of out-patients was discontinued at the Small-pox Hospital. In June, 1822, inoculation was discontinued to in-patients. On the 23d July, 1840, the practice of inoculation, the introduction of which has conferred immortality on the name of Lady MARY W. MONTAGUE, which had been sanctioned by the College of Physicians, which had saved the lives of many thousands during the greater part of the preceding century, was declared illegal by the English parliament. All offenders were to be sent to prison; and it was even provided that any attempt to produce small-pox by inoculation, even though unsuccessful, including, of course, the testing of vaccinated subjects, was an offence at law." (*Op. Cit.*, p. 39.)

11. II. DESCRIPTION OF NATURAL SMALL-POX. — This malady presents several forms, depending chiefly on its grades of severity, these grades arising from the intensity or concentration of the infecting miasm; from the susceptibility, constitution, or habit of body, of the person infected; and from the extent to which vital organs or surfaces are affected by the morbid actions developed by the morbific leaven. The state of the eruption more especially fixes our attention, inasmuch as it disorders the functions of an important organ, as it is a suppurative inflammation of a surface which induces serious sympathies in the œconomy, as it is an indication of the state and character of the vital powers, of the vascular action, and even of the blood itself; and as it most visibly and tangibly manifests the form or variety of the disease, suggesting not merely the diagnosis and prognosis, but also the indications of cure. As respects the *eruption*, therefore, it may be *distinct*, *corymbose*, *semi-confluent*, or *confluent*, according to the number, grouping, or distribution of the pustules; it may also be superficial, cellular, limited to the cutaneous surface, or extended more or less to the mucous membranes, especially at the outlets of canals; it may, moreover, be papular, vesicular, pustular, ichorous, scorbutic, or sanious, or purplish, or even blackish, according to the changes taking place in it. As regards the *type* or *character* of the attendant fever, small-pox may

be *benignant*, *synochoid*, *petechial*, *malignant* or *putro-adynamic*. It may also be *simple* throughout its course, and it may be more or less *complicated*, or associated with a prominent affection of one or more important internal parts or vital organs, developed during the progress of the malady. As will be rendered more apparent in the sequel, there is in general an intimate dependence of the state and appearance of the eruption upon the type and character of the fever, and of this latter upon the organic functions and the conditions of the blood. Whatever may be the form which the disease may assume, or however varied the associations of the states now enumerated may appear, small-pox presents certain stages which more particularly mark its course. These stagse have been divided into, 1st., that of incubation; 2d., that of invasion; 3d., that of eruption; 4th. that of suppuration; and 5th, that of exsiccation, But some authors have distinguished only three, namely, 1st., incubation; 2d., maturation, and 3d., decline. The stages may be divided into, 1st., the *latent*, *precursory*, or *incubative;* 2d., the *febrile*, or *the primary fever;* 3d., the *period of eruption and development;* 4th, the *maturative* or *suppurative stage*, or the *period of secondary fever, desiccation, and decline.*

12. i. DISTINCT, BENIGN, OR SIMPLE SMALL-POX. — This form of the disease is very frequently met with in healthy constitutions, favoured by a pure air. It was that most frequently produced by inoculation, when this mode of communicating the disease was permitted. Between it, however, and the confluent, no very precise demarcation can be assigned, as the corymbose and the semi-confluent are mere approaches to this more severe form. In the distinct or benign states of small-pox, there is no serious depression of the vital power, or contamination of the fluids or solids, or dangerous affection of internal or vital organs, which more or less prominently mark the confluent and typhoid forms of the malady. The distinct small-pox presents in general the regular procession of the stages just distinguished,

13. *A. The period of latency* or *incubation,* — the *precursory stage,* — in small-pox, or the time which elapses from the inhalation of the infecting miasm, or the morbific leaven, until the appearance of the primary fever has been ascertained with considerable precision on numerous occasions. In cases of inoculation, the duration of the stage is rendered apparent. But in natural small-pox it is very commonly a matter of doubt. Dr. GREGORY, who has directed his attention to this topic, states that a large accumulation of facts enables him to fix this period at about twelve days, and that the extremes may be stated at ten and sixteen days. It has been, however, contended by several writers, that circumstances may occasion much longer or much shorter periods of incubation than are here assigned; and my own observation tends to confirm this opinion. A concentrated effluvium or miasm from the infected; a severe and prevalent epidemic; a very susceptible, weak, or cachectic habit of body; great fear of the disease, or dread of infection; a warm, humid, and close atmosphere; and the respiration of air, loaded with emanations from a number of small-pox cases, may somewhat shorten this period, and hasten the next or eruptive. On the other hand, various circumstances may prolong this stage, and retard the appearance of the next, especially a weak dose of the poison; strong health and insusceptibility of the patient; a dry, cold, and pure state of the air, or residence in a dry and bracing locality. In the former circumstances, the period of incubation may possibly be shortened to seven or eight days, and in the latter it may be prolonged even to twenty or twenty-one days; but of these extreme ranges Dr. GREGORY very strongly doubts, ten and sixteen days being the extremes according to his observation. The inoculated disease furnishes a more determinate duration, which is generally from seven to nine days.

14. The first days of this period are often passed without much, or obvious disorder; but, in other cases, some symptoms are experienced indicating a state of impaired health, especially languor, lassitude, or malaise. When the disease is infected by a miasm floating in the air, or emanating from the sick, the patient sometimes experiences, at the time, an unpleasant and peculiar odour, generally attended by a feeling of sickness, giddiness, and of impending disease. When this feeling is strong, it is often accompanied by a state of alarm or dread, which seems to shorten this stage and to hasten on the next, and even to render the malady more severe.

15. *B. The febrile stage, or that of invasion — the primary fever,*—supervenes upon the preceding period; or from the ninth to the thirteenth day from the time of infection, or from the seventh or eighth day from inoculation, the patient experiences rigors, followed or attended by febrile symptoms, especially acceleration of pulse, heat of skin, pains in the loins and limbs, restlessness, scanty and high-coloured urine, nausea, vomiting, &c., &c. In some cases, the *rigors* and *heats* alternate for some time, or during the first day; but the latter generally soon follow on the former. On the second day the fever is attended by *nausea* and *vomiting*, and great depression, with tenderness at the epigastrium on pressure, and anxiety at the præcordia. The lassitude and torpor are often accompanied, in adults, with somnolency, headache and sweats; and in children, with faintness, sinking, or even with convulsions, or eclampsia. *Pain* throughout the body, more especially in the head, back, loins, and limbs, is always experienced, and the pain at the epigastrium is often so severe as not to admit of the least pressure, or even the weight of the bedclothes. In some cases, the headache is attended by stupor or delirium, especially in adults; and in children, by sopor, or epileptic convulsions; in these, the face is hot and flushed, and the carotid and temporal arteries beat strongly, the *tout-ensemble* of the symptoms indicating great vascular reaction. SYDENHAM remarks that, when children, especially after dentition, are seized with convulsions during the primary fever it is a sign of the speedy appearance of the eruption; so that supposing the convulsions to take place over night, a kindly small-pox may be expected to appear in the morning.

16. In other cases, excessive prostration, with faintness or syncope, extreme anxiety at the præcordia, oppression at the chest, frequent sighing, and even dyspnœa, pallid countenance, coldness of the extremities, and feeble pulse, usher in the febrile stage, and take the place of rigors or chills, or follow immediately upon them. These symptoms are indications of the depressing influence of the

poisonous miasm on the organic functions, and of the inability of the vital energies to react sufficiently, or to develope a state of healthy action. In these cases, a confluent state of the disease, or marked adynamia may be expected, with pulmonary congestion, &c. One or other of the foregoing groups of symptoms generally usher in the eruptive fever, and although neither of them can be considered as evidence of the nature of the incipient malady, still, the previous good health of the patient, the suddenness or severity of the seizure, the prevalence of variola in the vicinity, or prior exposure to infection, even although vaccination or previous small-pox should have been undergone, ought to be viewed as very strong indications of the disease. Dr. Gregory justly remarks, that the fact of prior vaccination should not throw the physician off his guard, for the initiatory fever is just as severe after vaccination as it is in the unvaccinated.

17. C. *The period of eruption and development.* — Forty-eight hours elapse from the rigors to the first appearance of eruption. The period is never less, but it may be protracted by weakness of constitution to seventy-two hours, and the full development of the eruption over the whole surface, may even occupy three days. Generally, however, the eruption appears on the third or fourth day of the fever. During this fever, besides the more prominent symptoms above mentioned, stridor of the teeth in children, with sopor, is very common; and in adults, a peculiar and fœtid odour, with sleeplessness, dryness of the fauces, and turbid state of the urine. The pulse is much increased in frequency, and is either soft, or broad and compressible. The febrile symptoms more or less abate in the morning, and increase towards evening.

18. Minute papulæ, sensibly elevated above the general surface, or plane of the skin, show themselves, at first on the face, forehead, and wrists, especially on the sides of the nose, upper lip and chin; then on the neck and breast, and afterwards, on the limbs and trunk. When the papulæ are numerous, their first appearance is attended by tension and slight pruritus; and, upon moving the fingers over the skin with some firmness, the papulæ are felt to be not merely superficial, but based in the cutis vera. The eruption rarely commences in the lower extremities. Sometimes two or three large papulæ precede the general eruption, and advance to the state of vesicle, before the surface is extensively occupied. The papulæ are "generally not thrown together confusedly and without order, but are arranged in groups of three or five. Crescents and circles may be traced very distinctly, when the eruption is not too copious. This constitutes an important diagnostic between variola and varicella." In most cases, the eruption affords great relief to the general constitutional disturbance. The fever abates, the sickness subsides, and the pains of the head, loins, and limbs moderate, or altogether cease.

19. *The development* of the papulæ commences with the evolution of the eruption and the subsidence of the fever, which precedes and evolves the eruption. But during this period, although the fever abates, more or less remarkably, especially in the benign, or distinct form of the distemper, yet it rarely ceases altogether, or disappears without returning more or less slightly in the evening. When the eruption is abundant, or the temperament of the patient is irritable or sanguineous, the mitigation of the fever is less remarkable; and, if the eruption has been delayed, or is confluent, or if the disease be complicated by some internal congestion or prominent affection, the febrile action may be continued during the development and maturation of the eruption with but little abatement, and generally in a typhoid, adynamic or even putro-adynamic form or type.

20. The number of the pustules vary according to the severity of the case — from three or four to some thousands, appearing first on the face, neck and upper extremities, then on the trunk, and lastly on the lower extremities, and changing from the state of papulæ, or vari, to that of vesicle and of pustule in succession. When the eruption is fully out over the body, and the pustules on the face begin to maturate, or about the eighth day from the commencement of the eruptive fever, the whole face, head, and neck become somewhat swollen, particularly the eyelids, which are often so distended as to close the eyes; and the swollen parts are painful when touched, and even throb. This intumescence lasts about three days, the spaces between the pustules appearing inflamed, or of a deep red, or damask rose colour: the closer this resemblance, the milder, generally, is the subsequent disease. Nearly one fifth of the number of pustules appear on the face; and according to Sydenham, the danger is in proportion to the number of pustules on the face, those on the other parts of the body hardly influencing the event. This, however, is not altogether the case, for the danger chiefly arises from the *tertiary* effects of the poison, or those produced upon vital or internal parts; the *secondary* effects being the cutaneous eruption.

21. *D. The suppurative or maturative stage,— the period of secondary fever and desiccation.* — With the intumescence of the face, the fever, which had remitted, returns, and the secondary fever commences. In cases of ordinary severity, the return of the fever is marked by a considerable increase of heat of surface, by a frequent pulse, and by slight delirium, from which the patient is easily roused. In favourable cases, the swelling of the face, the redness of the intervening spaces, and the secondary fever, having continued from the eighth to the eleventh day, subside, and the pustules, now fully ripe, burst and discharge a thin yellow matter, which concretes into crusts that fall off on the fourteenth or fifteenth day from the commencement of rigors, and the disease terminates, leaving the surface underneath the crusts depressed and of a pale lake colour. If the disease be of greater severity, hæmaturia, hæmoptysis, oppression in the chest, or a hard dry cough, may be complained of, with severe headache or pains in the loins or limbs, and more marked delirium, or even sopor; these more severe symptoms, however, generally subsiding on the eleventh or twelfth day.

22. When the symptoms assume an unfavourable aspect or threaten a fatal issue, then the face, which ought to have been intumescent on the eighth day, remains without any fulness or swelling; and the spaces between the pustules, instead of being red or inflamed, as seen in the favourable cases, are pale and white. Sydenham says that

the pustules look red and continue elevated even after death; and the sweat, which was free up to this day, suddenly ceases. At this critical period, the secondary fever, instead of presenting more or less of a sthenic character, may assume either a typhoid or an asthenic or a sinking form. When the secondary fever presents a typhoid type, the tongue becomes brown and dry, the pulse very frequent, and delirium soon appears, and often quickly passes into sopor or coma. In the rapidly sinking form, the patient may appear as suddenly overwhelmed by the depressing influence of the morbid poison, the pulse being hardly increased in frequency, the heat of the body natural, and the intellect unimpaired. DR. R. WILLIAMS remarks, that the first case he saw of this kind, he could not help assuring the patient "that his symptoms were favourable; but he shook his head, and, perhaps from an inward feeling that his fate was sealed, affirmed that to survive were impossible, and he died a few hours afterwards." (*On Morbid Poisons*, p. 228.) Such cases are, however, rare in the discrete small-pox, but they are much more frequent in the confluent (see §§ 33. *et seq.*), and result from the influence of the poisoned and contaminated blood on the organic nervous system and heart. These cases very closely resemble, in all respects excepting the eruption, the character and termination of the putro-adynamic form of *fever* (which see §§ 472. *et seq.*).

23. In the more severe cases of the discrete or distinct small-pox, the morbid poison acts not only on the skin, but also on the mucous membrane of the eyes, throat, and mouth, occasioning an eruption, often somewhat pustular, in these parts. This additional affection does not appear to aggravate the fever, at least not materially, but it occasions more or less inconvenience. The eruption in the mouth and throat causes hoarseness, soreness of throat, and difficulty of swallowing. When the eruption extends to the conjunctiva or cornea it is often not attended by much pain; but when the swelling of the eyelids has subsided, the extent of mischief which sometimes takes place, especially when the cornea is implicated, is then discovered. The mucous surfaces are, however, not so much or so generally affected in the discrete as in the confluent form of the distemper (§§ 39. *et seq.*).

24. At this period a peculiar faint and sickly odour, particularly when the eruption is copious, emanates from the patient. Sometimes, especially in females and persons of a delicate and scrofulous habit of body, the secondary fever is accompanied with a very tender state of the general surface; but it is a very favourable sign. Recovery may be retarded by weakness of habit, by cold, and by the presence or development of the scrofulous taint. An ecthymatous eruption may also occupy the surface, or the skin may be left dry and scaly, or the scabs may be adherent. These phenomena are chiefly owing to the form of secondary fever, in connection with the habit of body, &c.

25. E. *Of the progress and appearance of the discrete eruption.* — The affection of the skin being generally present, whilst that of the mucous membranes is often wanting, especially in milder cases, the cutaneous eruption requires especial attention. The *eruption* runs a course of eleven or twelve days, in discrete small-pox, from the very first appearance of it until its termination; and, in its progress, is at first tubercular or papular, then vesicular, afterwards pustular, and lastly, it scabs and falls off. The first, or papular, lasts about two days; the second, or vesicular, occupies four days; the third, or pustular, or suppurative, lasts three days; and the desiccative lasts three days more. The form and progress of the eruption is different in the confluent, in the verrucose small-pox, and in variola after vaccination. The eruption at first consists of a number of minute pimples or papulæ, which feel like minute tubercles in the true skin, when the fingers glide firmly over the surface, and are about the size of a pin's head. They are more or less numerous, but distinct from one another, and hardly salient. On the third, or close of the second day, a minute vesicle forms on the apex of each pimple or papula, which, as it fills, is bound down or depressed in its centre, or umbilicated, and contains a clear whey-coloured fluid. On the approach of suppuration or maturation, the cuticle covering the vesicle loses its transparency, and becomes white and opaque. About the fourth or fifth day of the eruption, a red areola appears around the base of each vesicle, and, shortly afterwards, the central *bride*, causing the umbilication of the vesicle, ruptures, and the vesicle becomes pustular, enlarges, and fills, and assumes a somewhat conical or acuminated form. From the fifth to the eighth day of the eruption, the pustule maturates, when the surface becomes rough and yellow, and the cuticle breaking, allows a portion of the contents to ooze out. In the interval from the eighth till the eleventh day, the pustule secretes the peculiar viscid matter which concretes and forms the scab. This scab desiccates, and is detached between the eleventh and fourteenth day, leaving the cutis, which it covered, of a reddish brown, which lasts many weeks; but if the pustule has so penetrated, as to cause ulceration of the rete mucosum, it leaves a permanent depression or pit. The cicatrix which is formed after these burrowing pustules is usually white.

26. F. *The internal structure of the variolous pimple and pustule* has attracted the attention, first, of COTUGNO in Italy, and afterwards of JOHN HUNTER, ADAMS, BOUSQUET, GENDRIN, JUDD, PETZHOLDT, and others. Dr. GREGORY has given the following account of the organisation of the variolous pustule: — "Inflammation begins at the spot called the phlyctidium. In seat is in the cutis vera. From the central point, or stigma, the inflammatory action proceeds by radiation to the surface, penetrating to a greater or less depth in different cases. Beneath the epidermis, and constituting the greater part of the phlyctidium, is formed a substance or disc, of the consistence of pulp or thick mucus. This is not considered as any part of the skin altered by disease, but as a product of a specific action of the vessels. JOHN HUNTER and ADAMS called it the variolous slough. At the height of suppuration this substance is swollen, and moist like a sponge. The floor of each phlyctidium presents the papillated structure of the skin, elevated and marked with fissures. The vesicle is divided, like the substance of an orange or poppy-head, into numerous cells — twelve or more. It is multilocular. A filament of cellular tissue binds down the central portion of cuticle to the lower surface of the phlyctidium, and gives to the vesicle, in its early stages, that umbilicated form — that de-

pression of its centre which, though not peculiar to the variolous eruption, is so striking a diagnostic mark between it and genuine varicella. The fluids, lymph and pus, which at different periods distend its cells, destroy at length the filamentous attachment of the stigma to the cuticle, and that which was at first a depressed or umbilicated vesicle becomes at last an acuminated pustule. It bursts, discharging a well-formed purulent matter, of a yellowish colour and creamy consistence."*

27. The inflammation of the phlyctidium is attended by a specific or erythematous inflammation, called the areola, extending to some distance beyond the margin of the vesicle. The exact tint of this areola should always be carefully noted as indicative of important local and constitutional states. On the subsidence of this inflammatory areola, the ripened pustules, having burst and discharged their contents, are succeeded by scabs, which dry up and fall off, in a healthy constitution, in four or five days. In very mild cases, when the process of pustulation is not fully gone through, many of the vesicles shrivel, and form only imperfect, scaly crusts. On the lower extremities, this premature desiccation of the vesicles is often very general.

28. In severe cases, the inflammation of the corion does not cease with the completion of the pustulating process. Portions of the cutis vera are then actually destroyed and slough away, the skin presenting the appearance of pits or fossæ, with a clarety hue, when cicatrization is at length completed. The dark tint wears off in the course of three or four months, but the depressions are permanent. From the great vascularity of the face, and from the exposure of it to light and air during the progress of the eruption there is always a more severe effect and disfigurement produced by the disease in this situation, than in any other part of the surface of the body.

29. ii. MODIFICATIONS OF DISCRETE OR BENIGN SMALL-POX. — *A. Verrucose Small-pox — Variola verrucosa.* — *V. cornea.* — *Horn-pock, &c.* This mild, mitigated, or modified form was well described by VAN SWIETEN. Its symptoms are similar to those of the preceding form, but are much milder. The primary fever is often little more than a febricula, and the pustules seldom exceed one or two hundred. These, indeed, seldom reach a pustular state, but, having passed through that of tubercle or papula into that of vesicle, on the sixth day, or even sooner, desiccate, shrivel up, and crust. This form is so mild, that the secondary fever is not manifested, and consequently is wanting; convalescence commencing on the eighth day of the eruption.

30. *B. Variola discreta siliquosa.*—When there are empty vesicles between the pustular pimples, or when the pus of the pustular pimples has been absorbed, so that they are left empty, the disease has been named *discrete siliquose small-pox.* When the eruption continues *vesicular*, instead of being pustular, the disease has been called *discrete crystalline small-pox.* When vesicular pimples appear in the interstices between the pustules, this modification has been named *discrete vesicular small-pox.* In these varieties the symptoms are generally mild, and the eruptive fever generally slight or moderate, and the secondary fever is either wanting or mild; the duration of the disease being rarely prolonged, but often somewhat shortened.

31. *C. Small-pox without the eruption.*—*Variola sine Eruptione.*—Variola presents, in the more severe cases, the fever, the cutaneous eruption, the affection of the mucous membranes, and the internal complications, hereafter to be described. In the more mild or benign cases, it consists only of the fever and the eruption; but, in both classes of cases, there is a *primary* and *secondary* fever. In small-pox the fever is remarkable, and distinguished from all other fevers by its remission at the end of four days, or when the eruption has come out, and by its return after a remission of four days, or about the end of the eighth day in the discrete, and about the eleventh day in the confluent small-pox. But cases sometimes occur, especially where the pustules are few, or their maturation is rapid or abridged, in which the secondary fever is either very slight or altogether wanting; and other cases are met with, much more rarely, where neither the eruption, nor the secondary fever, is detected; and yet there can be no doubt of infection having taken place, and of the system being protected from another attack. In those, however, the primary fever has

---

* The following descriptions further illustrate this topic: — BOUSQUET says that the pustule has its seat in the true skin, and that the epidermis is not thickened. On removing, however, the epidermis, which is easily detached, we discover a white, opaque, smooth surface, which is a layer of lymph deposited from its adherent surface, and on removing this "disc," the interior of the pustule is seen divided by many concentric radii into a number of divisions or cells, each filled with fluid, but not communicating. This interior arrangement, BOUSQUET compares to a cut orange, or pomegranate, while Gendrin says, it resembles that of a spice box. The depression at the centre on the *umbilication* is occasioned by a portion of cellular tissue which binds down the cuticle, and is slow to undergo the process of ramollissement by which it ultimately ruptures. The description of the pustule by Mr. JUDD, who appears to have examined the formation of the small-pox pustule with great care, is, in some respects, different. For he states, "that in the small-pox pustule, circles of vessels enlarge and project from the cutis vera, and they secrete a thin serum, which gradually raises a ring of the cuticula externa from the rete mucosum, and distending it, forms a vesicle, without, except in some violent confluent cases, breaking up the attachment in the centre between the cutis rete and the cuticle. Hence the vesicle is bound down at that spot, and hence it has a depressed summit. The degree of inflammation suddenly increases, and a thick coagulable lymph is then thrown out that at once consolidates, and forms a thin flat plate like a cymbal, but with a small hole left through its centre, from the coagulation taking place around the before-mentioned thread-like attachment of the cuticle. Now, about the time when the fever and inflammation are again increased, called the secondary fever, and pus being secreted, it elevates the lately described cymbal, or plate, and causes it to divide the pustule horizontally, into an upper and lower cell, and the progressive distension at times breaks up the remaining attachment between the cuticle and cutis. The pustules become opaque; for the pus passes through the hole in the plate, or septum, and blends with the lymph or serum above. The lower part of the pustule is completed by an extremely thickened state of the rete mucosum, which forms a raised lip or cup around; and, in most instances, the pustule may be stripped off with the cuticle and rete, still leaving the cutis entire. But the cutis vera has frequently a slight depression left from ulceration at the base of the cup, and occasionally a papule of the cutis projects into its centre, to which the band of attachment from the cuticle still adheres.

"After the incrustation has separated, and the eruption is gone, a stain with a depression, is commonly left in the centre of the rete mucosum, occasioned by a zone of red vessels remaining long distended, both in the Ethiopean and in the European. In the former it is black and permanent, except when the cutis vera has been penetrated; whilst in the latter the marks are red and transitory, unless, indeed, when ulceration has penetrated the cutis, in which case, in them, also, the pits are white and permanent in the European."

taken place, but without inducing the usual eruption. SYDENHAM, LENTIN, PELARGUS, DUBOUSIS, DU BOURG, FRANK, and others have observed, during the epidemic prevalence of small-pox, that some few persons who have not previously had the disease, nor been vaccinated, have been seized with all the symptoms of the primary variolous fever, and which having subsided without any eruption having appeared, they have afterwards been found unsusceptible of the disease.

32. SYDENHAM, DE VIOLANTE, CROSSE, and some other writers above referred to, have remarked that cases have occurred, during the periods when small-pox was raging, which have been attended by petechiæ, bloody-urine, or by purple spots and low fever, and have terminated fatally. These cases were viewed by them as small-pox without the eruption the severity of the internal complication, or the state of the habit of body and of constitutional powers preventing the due and regular evolution of the disease on the surface. It is by no means unreasonable to suppose, that analogous phenomena to those which I have described in respect of *scarlet fever* (see that disease § 26. *et seq.*), may also occur during the prevalence of epidemic small-pox; and that, owing to a predominant affection of the kidneys, or to depressed vital power, the eruption is either not developed on the surface, or very imperfectly, or in such manner as remarked by these and other writers. In cases where the kidneys are thus severely and early implicated, especially so as to arrest their excreting functions, not only are the usual phenomena and progress of the distemper interrupted, but a fatal issue soon takes place.

33. iii. SYMPTOMS OF CONFLUENT SMALL-POX. —This state of the distemper commences generally with symptoms similar to those of the distinct variola, but more severe. The primary fever is usually attended by more sickness and vomiting; by severe pain in the loins, head, and limbs; by greater heat of surface; by more considerable and continued delirium; and, in children, especially in the evening, or just before the eruption, by eclampsia or convulsions. The fever is not only more intense than in the discrete variola, but it is also of shorter duration; the eruption appearing somewhat earlier, or generally on the third day, sometimes at the end of forty-eight hours from the rigors, but rarely later than the third day. The sooner the eruption appears, the more confluent, generally, does it become. Sometimes it is preceded by extensive erythematous inflammation, and the papulæ come out irregularly, or in small clusters, or resemble the measles, and are more prominent than in the distinct variola.

34. The eruption is followed by a less complete remission of the primary fever than in the discrete small-pox, the pulse continuing frequent and soft, the tongue white, and the skin more or less hot, especially in the evening or night, when, also, delirium often recurs. Salivation, which seldom is seen in the distinct, excepting in the more severe cases of that form, very generally occurs in the third stage of the confluent distemper — during the period of development, beginning either with the eruption, or a day or two afterwards. The salivary discharge is at first thin and abundant, resembling that produced by mercury; but it becomes thick and viscid about the eighth day of the eruption; and, in very severe cases, it either ceases for a day or two and then returns, or it disappears altogether. Adults are more liable to salivation than children; but diarrhœa more frequently occurs in the latter, and often becomes profuse, or continues during the disease. The eruption is more or less modified in the confluent distemper; for the pustules, especially those on the face, do not rise, and are more irregular and flatter in their forms than in the discrete form. Owing to their greater number and contiguity, they run into each other and become confluent; sometimes forming irregular blisters or bullæ, varying from the diameter of a fourpence or sixpence to that of a half-crown.

35. These symptoms may not vary materially until the eighth day of the eruption, or eleventh of the fever, when the stage of secondary fever commences, and greatly increases the severity of symptoms and danger of the malady. Previous to this period, the confluent malady seldom endangers life unless hæmaturia, or suppression of urine, or hæmoptoë, or congestive pneumonia, or general bronchitis, &c., supervene, or the character of the pustules, or other signs, indicates a very contaminated state of the circulation. On and after the eleventh day, especially on that day; and on the fourteenth, the seventeenth, or the twenty-first day, according to SYDENHAM and R. WILLIAMS, the patient is often brought to such an extremity, that it is equally uncertain whether he may live or die. He is first endangered on the eleventh day by a high fever, attended by great restlessness or delirium, or by other symptoms, which usually prove fatal unless controlled or prevented by treatment. If he outlive this day, the fourteenth and seventeenth are to be dreaded, for distressing restlessness, with more or less of the unfavourable symptoms about to be noticed, are liable to come on, or to become aggravated, between the eleventh and fourteenth days, and to place him in the most imminent jeopardy.

36. The most dangerous symptoms in the advanced stage of the distemper, or appearing with or during the secondary fever, are, the absence of the usual redness in the intermediate spaces; the non-intumescence of the face; the distribution of petechiæ in the interstices, or a black spot, hardly so large as a pin's head, in the centre of each pustule, or the partial filling of the pustules with a dark ichorous matter, or a disposition to gangrene in the larger vesicles; suppression of the salivation; cough, with hæmoptoë; suppression of urine, or hæmaturia; the signs of congestive pneumonia or bronchitis on percussion and auscultation, more especially if attended by lividity of the lips, face, or extremities, indicating the affection of both lungs, which is generally the case; a brown or dry tongue; great restlessness, or a continued delirium, coma, or sopor; unconscious evacuations; exudations of a dark or ichorous blood from the mucous canals, &c. From certain of these, particularly those first mentioned, recovery may take place when the treatment is judicious and energetic, but the convalescence is long, and its progress is often delayed by ulcerations of the cornea, or general asthenic ophthalmia causing blindness; by purulent depositions in the joints, or ulcerations or erosions of the cartilages, producing lameness; by otitis terminating in deafness; by abscesses in various

quarters, and by suppuration of the subcutaneous cellular tissue, causing cicatrices and alterations of the features. (*See the Complications, &c.*, § 42.)

37. The disease may assume a *semi-confluent form*, or one intermediate between the discrete and the confluent. This form is generally *superficial*, although not always or necessarily so, and much less frequently implicates the sub-cutaneous cellular tissue than the confluent. When thus superficial, whether semi-confluent or confluent, the eruption passes through its regular stages, but the inflammation does not extend deeper than the cutis vera. This superficial confluent form appears in the unvaccinated and sometimes in the vaccinated; and the pustules over the whole body maturate equally and regularly, pursuing their usual course, and occupying the full time to their termination or desiccation. "This form of the disease was well known before the days of JENNER, and is not to be confounded with the confluent small-pox, as modified by vaccination." (GREGORY.) It takes either the same time to maturate as the distinct, namely, seven days, or an intermediate period between the discrete and the confluent, videlicet, about eight days, the confluent generally requiring nine or even ten.

38. iv. VARIOLA AFTER VACCINATION. — The symptoms of this form of the disease may vary with the time which has elapsed from vaccination, but in the majority of cases they are the same as those characterising the variola verrucosa, or the horn-pock (§ 29.), or that very mild or mitigated form which maturates in five or six days, or in a shorter period. I have seen, on several occasions, and even described, as early as 1823 (*see Lond. Med. Repos.*, vol. xxi.), small-pox as it affected the members of the same family at different periods after vaccination; and in the younger persons, or those who had been vaccinated only ten or eleven years, the primary fever produced an eruption which was merely papular, or hardly vesicular, whilst in the older, or in those who had been vaccinated a longer period, the primary fever was more severe, and the eruption either vesicular and verrucose, or pustular in a distinct or even confluent form; the severity and fully-developed state of the disease being generally in proportion to the length of time which had elapsed from vaccination. In the former class of cases, the disease is thus more or less modified, and the secondary fever, either slight or absent; but in the latter, or pustular, the modification is either slight or hardly apparent, the secondary fever being more or less severe. I have, moreover, seen cases, after undoubted vaccination, having been effected from thirty to forty years previously, that presented the most malignant states of the confluent disease, the pustules maturating imperfectly or slowly, or being filled with a black ichorous matter, the distemper presenting the characters described when treating of *putro-adynamic fever*. (*See art.* FEVER, §§ 472. *et seq.*)

39. III. THE COMPLICATIONS OF SMALL-POX. — *A.* In a large proportion of confluent, and in some semi-confluent cases, the *mucous surfaces* are more or less implicated in the progress of the malady. The parts to which the air has ready access are most frequently affected, as the nose, mouth, trachea, &c.; but other parts covered by mucous membranes are also attacked, as the œsophagus, stomach, intestines, &c.; this *mucous complication* has been well described by Dr. GREGORY. The eruption appearing on these surfaces is sometimes distinct, but more frequently confluent. Numerous white points appear on the tongue, palate, velum pendulum, and pharynx. Hoarseness or alteration of voice indicates that the same or similar changes extend to the mucous surface of the larynx and trachea; and the pain in swallowing shows that the pharynx and œsophagus are also affected, especially in severe cases. In these especially, a cough, which is at first dry, tearing, or clangous, is present with more or less dyspnœa and oppression in the chest. As the malady progresses, the cough becomes more loose, but sometimes also more suffocative, and about the seventh or eighth day expectoration is more or less abundant, frothy, and viscid, containing some whitish specks. This affection of the respiratory surfaces often evidently increases, and extends over a larger surface; and constitutes a peculiar or specific form of acute *laryngo-tracheal bronchitis*, which may exist either singly or separately, or be associated with a *congestive pneumonia*, or superinduce this latter. When once this complication is present, and more especially when it is thus severely extended, most dangerous results are then generally observed. It is apt to occur in the most severe cases, or where the constitutional powers are weak, and the febrile symptoms present more or less adynamia. In these circumstances, this complication is the more liable to extend downwards; and, from the trachea, it is prone to advance to the bronchi of both lungs; the *bronchitis*, or the *pneumonia*, or the *broncho-pneumonia*, thus superinduced, being not only asthenic or congestive, but generally double, or implicating both sides; hence the severity, the rapidity, and the fatality of the results.

40. Even when the complication is limited to the mouth, throat, and larynx, or proceeds no further than the trachea, the œdema or swelling of the sub-mucous tissues may be so great, particularly about the seventh or eighth day, as to impede the free access of air to the lungs, and the same consequences ensue, especially in respect of the blood, as follow the extension of the complication to the bronchi and lungs. In either case, the blood does not undergo the requisite changes in the lungs, — it is no longer, or only imperfectly, oxidised or arterialised, and the following phenomena supervene: — The vesicles are flat, or, at least, do not acuminate, their contents are dark or ichorous, and the areolæ which surround them on the trunk and face are dark, or claret-coloured. Sometimes the surface presents a dark, erysipelatous appearance, attended by large watery blebs, or bullæ, from which an ichorous fluid escapes. On the succeeding day the tongue swells, and, with the lips and gums, exhibits a purplish hue; the extremities and nails become livid; low, muttering delirium is present; and either restlessness, anxiety, and dyspnœa succeed, or coma, distended bladder, or relaxation of the sphincters, takes place, and death soon afterwards supervenes.

41. The *digestive mucous surface* has presented changes more or less nearly approaching the pustular character, according to the accounts furnished by RIVERIUS, BRENDEL, WRISBERG, BLANE, and many others, and these have been

met with on the œsophagus, stomach, and small and large intestines. But the changes there observed, whether eruptive or pustular, have not been described with sufficient precision. Granting it to have presented somewhat of an eruptive appearance, it could not, however, have been pustular; for the nature of the tissues,—the structure of the parts, — admits not of a pustular formation. It is much more probable that, in the course of this as well as of other eruptive fevers, the glandular structures of the digestive canal become more particularly implicated, the morbid state of the blood exciting a special affection of these structures in the course of their functions, which have a very strict reference to the conditions of this fluid. In the most malignant or putro-adynamic state of this distemper, I have observed, especially in the dark races, the exudation of a dark, dissolved, or sanguineo-ichorous matter from one or several of the mucous canals, at an advanced stage of the distemper; an occurrence also observed in, and described when treating of, *putro-adynamic fever* and *hæmogastric pestilence*, and resulting from changes of a similar nature. In these, the alteration of the blood, and the loss of tone in the capillary circulation, admit of the exudation of blood from those parts or tissues especially, which, owing either to previous affection, or to loss of vital cohesion, are most prone to experience this change. (*See art.* HÆMORRHAGE, §§ 13. *et seq.*)

42. *B. The sub-cutaneous cellular tissue* is often implicated differently from, and even more seriously than, that which has been already cursorily noticed (§ 36.). In the discrete form, this tissue is rarely affected, but in the confluent or semi-confluent, and in the variety which Dr. GREGORY calls irregular or corymbose, the morbid action often extends deeper than the skin, and invades the cellular substance either partially or to a very considerable extent. According to this limitation or extension, the integuments are swollen and tense. When the scalp is affected, it becomes remarkably swollen, and resembles erysipelas of this part, excepting that it is attended or followed by a diffuse or confluent pustulation, or a succession of small abscesses. The salivation already described (§ 34.) is often accompanied with great swelling, more or less diffused, in the throat and neck. In some instances the tongue is involved; and when a diffused inflammation of the neck and throat thus extends to the tongue, an unfavourable issue then soon follows.

43. The cellular tissue in various other parts, especially where pressure is experienced, or where the vital cohesion of the tissue is the weakest, often becomes the seat of an asthenic inflammation, particularly in the more severe or malignant confluent cases. The sacrum, back, hips, elbows, scrotum, legs, and various other parts, may be the seats of boils or carbuncles, or of sphacelation. This change is most apt to appear during the secondary fever. Dr. GREGORY remarks, that he saw, at the Small-pox Hospital, an exact counterpart of the pestilential bubo and carbuncle in the groin of a small-pox patient. The face always suffers in these cases very severely; and if recovery takes place, it is not only pitted, but also seamed and scored by the cicatrizations consequent on the inflammation of the subjacent cellular tissue. Dr. GREGORY states, what I have also often noticed, that the disposition to suppuration of parts affected during the secondary fever of small-pox, appears to be universal and almost uncontrollable. In some few cases, the larger joints fill with purulent matter. Of the gangrene which so often occurs in the severe cases of variola, it may be remarked, that attempts should be made to prevent it, by attention and proper nursing and regimen, for in such cases it is often induced or aggravated by the absence of these, especially when the patient breathes an air rendered impure by putrid animal emanations, or contaminated by being too frequently respired, or breathed by too many persons.

44. *C. Ophthalmia* is a frequent and most important complication of small-pox. It has been unjustly stated, that the inflammation of the tissues of the eye is attended by the formation of pustules on the cornea and conjunctiva. But, although these tissues are very susceptible of the inflammatory states complicating this malady, they cannot admit of pustular formations. When inflammation implicates the eye, it may either be limited to the conjunctiva, or extend deeper, and even affect the whole organ. It is most disposed to take place when the changes in the skin arrest the natural functions of this surface, and when, with the secondary fever, there is a manifest contamination of the circulation, or some internal complication. The ophthalmia of variola may be the only prominent local affection, or it may be associated with others of an important or more dangerous nature. Dr. GREGORY remarks, that ophthalmia commencing on the tenth day of the disease sometimes advances so rapidly, that in forty-eight hours the whole eyeball is irrecoverably injured. The whole eye may even be converted into one large abscess. "More usually, the inflammation runs into some one of its less violent and more familiar consequences. An ulcer forms at the outer edge of the cornea, by which the aqueous humour escapes, or at which a staphylomatous protrusion of the iris takes place; or the aqueous humour becomes clouded, or specks form on the cornea, from which blindness, more or less complete or permanent, results. Many things concur to render it almost certain that the affection of the eye in small-pox is connected with some altered condition of the blood, and the retention of the vitiated matters which ought to have been eliminated." Of this there can be no doubt; for, as I have shown in various parts of this work, the depression of organic nervous power, and the contamination of the blood, superinduce all the complications observed in the advanced course of both continued and eruptive fever, and of other maladies impairing the functions of excreting and depurating organs.

45. *D.* It must be manifest that the *circulating fluids are more or less contaminated* by the poison of small-pox, whether that poison be communicated by the mucous or by the cutaneous surface. This contamination must necessarily exist in all cases of the malady, but in a very inappreciable amount in slight and benign cases; the eruption on the skin being its more prominent effect. Where, however, the vitiation is greater, and especially where the eliminating or excreting organs imperfectly discharge their functions, or where vital power is much depressed by either the primary or secondary operation of the poison, the circulating fluids, and particularly the blood, be-

come very remarkably and even sensibly altered. This alteration is manifested in various ways, but more especially in the advanced course of the malady; although it may be perceptible from the commencement of the primary fever. It is, however, more frequently noticed when the eruption appears, or at a later period, or when the eruption is proceeding to maturation. It is this contamination of the blood which, when more fully consummated, imparts the character of malignancy or of putro-adynamia to the distemper. This vitiation of the circulating fluids is rendered apparent, 1st., by the state of the blood when drawn from a vein; 2d., by the change in the appearance of the eruption; 3rd., by the hue of the surface in the spaces between the pustules, and by the lividity of the lips, tongue, and extremities; 4th, by the petechiæ, vibices, or ecchymoses, intermixed with the variolous papulæ or vesicles; 5th, by the filling of the vesicles with a bloody matter, or with a dark ichor, or even with dark, dissolved blood; 6th, by the passive hæmorrhages which occur from the mouth, or nose, bowels, or or urinary organs, or from the vagina, or from two or more of these outlets.

46. *a.* The more visible changes in the *blood* drawn from a vein are similar to those which I have described when treating of the *pathology of the* BLOOD (*see* §§ 125. *et seq.*), and consist chiefly of impaired crasis of the crassamentum, or a loose, gelatinous portion covering the black and hardly coherent portion of the coagulum. The alteration is often still more manifest in the blood poured out from one or more of the mucous canals, this fluid appearing as partially dissolved, dark, or ichorous, and being incapable of coagulating. — *b.* The *eruption* has at first a dingy or livid aspect; and as it proceeds to imperfect maturation, the vesicles fill only partially with a dissolved bloody serum, or with a matter containing the blood-globules changed to a blackish or brownish hue; and the vesicles are intermingled with petechiæ, &c., already mentioned. — *c.* The *general appearances* of these cases is often peculiar, and they are the most distressing and frightful manifestations of disease which can present themselves to our observation. The expression of the countenance is most anxious. The tumefaction of, and eruption on, the face; the exudations of blood from the mouth and nostrils; the closed, livid, and tumid eye-lids; the discharges from under them, or from the eruption; the swollen, softened, livid, or blackened hue of the general surface; the ichorous or bloody exudations from the urinary and genital organs and bowels, — all combine to impress the mind with an idea of a pestilence, exceeding in severity, and frightfulness of its aspect, both the plague and yellow fever; and to suggest the idea of a general dissolution or putrefaction of the structures, even before life has taken its departure, — a dissolution which has already partially taken place, in so far as that the tissues have actually lost a very large share of their usual vital cohesion, and have entered upon changes identical with those which appear soon after death.

47. The appearances now described are but rarely observed in the variola of the *white races;* yet I have met with them in a few cases, and in two or three instances the patients had been vaccinated many years previously. This malignant form of the malady was of more frequent occurrence formerly — before the introduction of inoculation and vaccination — than now, and was more common in some epidemic visitations of the distemper than in others. It was called by older writers, the *variolæ nigræ,* or black small-pox; and is, even now, the not uncommon form of the disease amongst the *dark races,* especially the *Negro,* and particularly when the distemper spreads by the respiration of miasms from the infected. When the adult female is the subject of this state of the malady, a most depressing or exhausting menorrhagia is apt to take place. I attended, some years ago, with Dr. GREGORY, a lady who was carried off by this form of small-pox. She had been vaccinated about thirty years previously, but she nevertheless presented the appearances just described. In this case, as in the following, mentioned by this physician in his work, the functions of the brain were not disturbed. "In February, 1842," Dr. G. remarks, "I saw, in consultation with Dr. L. STEWART, a lady in small-pox, whose whole body was the colour of indigo, and whom I at first believed was a native of Africa. She conversed with me in the most tranquil manner, and died a few hours afterwards, proving that the nervous system is not necessarily, nor is it even usually, implicated in the petechial form of small-pox" (*Op. Cit.*, p. 52.) This exemption of the brain from disturbance is very often met with in other malignant fevers, more especially in putro-adynamic fever, in malignant puerperal fever, in the hæmagastric pestilence, in plague and pestilential cholera, — maladies in which the circulating fluids are most signally vitiated. Dr. GREGORY has remarked, what I have reason to believe to be correct, namely, that death may take place in consequence of this remarkable condition of the blood, before any unequivocal signs of small-pox are developed, and has adduced two instances in which this appears to have occurred. Under common circumstances, the malignant or petechial form of variola exhibits an abundant confluent eruption, but this never makes much progress towards maturation. "Nature apparently gives up the struggle as hopeless. The patient is carried off very unexpectedly, perhaps on the fourth day, or from that to the sixth." But I have seen such cases sometimes protracted to the seventh or eighth day.

48. *E.* The *brain and nervous system* are often prominently affected in small-pox. This may occur at any age. Children are seized with convulsions on the accession either of the primary fever, or of the secondary fever; or they grind their teeth, roll their heads, scream, and squint. On these, inflammatory action, effusion, &c., supervene; or these changes have already taken place, to some extent, and occasioned these symptoms. In such cases, death very generally follows, either during an attack of eclampsia or convulsions, or with the usual signs of cerebral congestion and effusion. In older children and adults, the accession of the cerebral complication is attended by delirium of a violent or maniacal form — the *delirium ferox.* In some cases, the delirium is owing more to irritability of temperament, or peculiarity of constitution, than to inflammatory action; and in others, the nervous symptoms are attended by great depression of spirits, and by an inclination to commit suicide.

49. Dr. GREGORY remarks, that "*a peculiar nervous affection* often supervenes on the tenth day, when the skin is extensively occupied by the confluent eruption, without nervous complication. It is identical with that which is familiar to surgeons as the consequence of extensive burns and scalds. General tremors, low delirium, a quick and tremulous pulse, a dry tongue, collapse of the features, cold extremities, and subsultus tendinum, are the symptoms of this nervous complication, and the precursors of a fatal event." (*Op. Cit.*, p. 51.) This is an accurate description of the unfavourable termination of a large proportion of confluent cases, as observed in weak constitutions, when the vital resistance is insufficient to oppose the depressing tendency of the distemper, or when the powers of life have not been sufficiently supported, or when support has failed to be efficacious. It is of great importance to recognise the accession of this state of sinking of vital power, in order to have a chance of opposing it with success.

50. *F.* Certain of the *bronchial and pulmonary complications* have been already noticed (§§ 36, 40.), especially such as arise from, or depend upon the contamination of the blood. But it is not unusual to observe a state of *bronchial irritation*, or *inflammatory action*, from the commencement of the febrile state, especially during the winter season. It may accompany the progress of the malady, without being materially increased, or without inducing a more violent form of the distemper. Frequently, however, and more especially in warm climates, or in the *dark races*, who have migrated to cold or temperate regions, the bronchitis extends generally to both lungs, and often to the substance of the lungs also, thus developing a form of congestive *broncho-pneumonia* (§ 39.). Sometimes associated with bronchitis, or with pneumonia, or occurring independently of either of these, *pleurisy* supervenes, and constitutes a most dangerous complication of variola. It has been noticed as follows by the able author just mentioned: — "Variolous pleurisy occurs between the twelfth and twentieth day. It is a peracute form of inflammation, remarkable for its sudden invasion, rapid progress, and invariable termination by empyema. The symptoms are very unequivocal: intense pain of the side, a hard or wiry pulse, shortness of breathing, great anxiety of countenance, a peculiarly pungent heat, and dry state of the surface, betoken but too forcibly the state of the pleura, even without stethoscopic aid. Blood-letting is almost powerless in this state of the disease. Death usually happens on the third, or, at farthest, fourth day from the invasion of thoracic symptoms." (*Op. Cit.*, p. 54.)

51. *Variolous pleurisy*, whether occurring as a complication or as a sequela, is not confined to the confluent, or any other form of small-pox. It may appear in the distinct or mild variety, or in the varioloid or modified disease, and in these forms it may be traced to exposure to a current of air, or to some other cause; and it may take place, especially when thus produced, at any stage of the malady. When it supervenes during the confluent distemper, and at the far-advanced stage, as just now described, it may justly be ascribed, as Dr. GREGORY has inferred, to the morbid condition of the blood at this stage, — a cause which sufficiently accounts for the rapid progress and fatal issue of the complication. The variolous pleurisy, however, may not only be acute, or attended by very sensible indications of its existence, but also *latent*, until the consequent empyema or effusion has produced very manifest effects upon the respiration and blood.

52. *G.* The *heart, pericardium*, and *blood-vessels* are more frequently affected in a very prominent manner than has been generally supposed. — (*a.*) The *endocardium* and *pericardium*, either or both, may be implicated in the progress of the more severe forms of variola, owing to the alteration of the blood, produced either primarily by the variolous poison, or, secondarily, by the absorption of a portion of the matter formed in the pustules, and by interrupted excretion; but, however induced, this complication is rapidly fatal, often without any other symptom than sudden sinking, and rarely with either pain or palpitation; more frequently with sudden anxiety and sense of dissolution.

53. (*b.*) That the internal surface of the *blood-vessels become asthenically inflamed*, as an advanced complication or sequela of small-pox, has been on several occasions witnessed by me at the infirmary for children since 1820; but I believe not so frequently as the endocardium and pericardium. The veins are certainly oftener implicated than the arteries, or, at least, more sensibly so, especially when the affection of the former gives rise to obstruction of the circulation through them. But, as I attempted to show many years ago, *asthenic phlebitis* may supervene in the progress of malignant distempers, and fail of producing lymph from their internal membrane capable of coagulating; the product of the morbid action being a fluid exudation, which passes into, and mingles with the blood circulating through the inflamed vessels, thus contaminating, or poisoning more fatally, the blood, heart, and blood-vessels.

54. *G.* The *purulent collections*, also formed within the capsules of joints, are rare complications or sequelæ of small-pox, yet they are not so rarely met with as to permit being overlooked. These deposits may be referred to the same series of changes, especially as regards the circulation, as have been noticed, and even fully discussed, with reference even to small-pox, when treating of purulent formations. (*See art.* ABSCESS, § 27. *et seq.*)

55. *H. Abdominal complications* are less frequent than the thoracic affections now passed under review. They are nevertheless sometimes met with, especially during the epidemic prevalence of the distemper; and oftener in some epidemics than in others. This circumstance is not always readily explained; although in some cases it may be referred to modes of living previously to, or at the period of infection, or to the water, or other peculiarities of the locality, or to the place of residence. — (*a.*) The most common of this class of complications are *diarrhœa* and *dysenteric affections*, sometimes leaving behind them, when convalescence has so far proceeded, diseased mesenteric glands, with emaciation and atrophy, as a sequela of the malady. Children, in unhealthy localities, are not infrequently affected by a mucous diarrhœa, or even with tenesmus and other symptoms of dysentery, in both the discrete and confluent forms of small-pox; the risk from this association being increased according to its severity.

In a few instances, blood is passed with, or intermingled with the stools to an amount which tends rapidly to sink the patient. If the stools be merely streaked with blood, the risk is less; but even these may indicate great danger.

56. (*b.*) Pain in the region of the *kidneys*, symptoms of congestion of these organs, and *hæmaturia*, are not uncommon in the severe states of the distemper, and are always to be viewed as most unfavourable occurrences, especially if the urine be scanty or suppressed. In cases of hæmaturia, the source of the sanguineous exudation has not been accurately determined, but there is reason to infer that it is the secreting structure of the kidneys; and that these organs are more frequently and seriously implicated in severe cases of this distemper than is commonly supposed. I do not say that they are so generally or so dangerously involved as in scarlatina, but this symptom, in connection with remarkable scantiness of the excretion, and an almost complete suppression of urine, have been remarked by myself and others sufficiently often to attract a more particular attention to the function of the kidneys during the course of the malady, and to the appearances they exhibit in fatal cases, than has hitherto been directed to them. It must be manifest, that even a partial impairment of the excreting offices of these organs, at any period of small-pox, must necessarily render the blood more and more vitiated, and superinduce various other dangerous or fatal results in vital organs, as I have fully shown when treating of *scarlet fever*. (See that *art.*, §§ 49. *et seq.*)

57. *I. Other complications* may occur, on rare occasions, in the course of variola, but they are very seldom detected during life, and more rarely looked for, or disclosed, on dissection. I shall only mention a few of those which have been noticed, and which should be kept in recollection during our dealings with this distemper: the presence of *intestinal worms*, which often aggravate the character of the disease, and which are often discharged at an advanced stage of the most severe and fatal cases; signs of inflammation, or congestion, or of functional disorder, of the *liver* or of its appendages, various changes in these parts being detected after death; intumescence of the *spleen*, and softening of this organ in fatal cases; one or other of the several forms of *erypsipelas*, or diffusive or asthenic inflammation of the cellular tissue; inflammation of the *urinary bladder*, and exudations of blood from the inner surface of this viscus; and a similar affection, with an imperfect development of pustules, vesicles, or papulæ, on the *labiæ valvæ* and *vagina*; this last being very frequent, and very troublesome in some cases.

58. ii. SMALL-POX MAY COEXIST WITH OTHER SPECIFIC OR EXANTHEMATOUS MALADIES.—This is a rare occurrence, but one which should not be overlooked.—(*a.*) *Measles* coexist with variola more frequently, perhaps, than with any of the exanthemata. This combination has been observed, both distempers running their normal course, and uninfluencing each other, by DIEMERBROECK, DE HAEN, WEBER, TRACEY, KING, DELAGARDE, JONES, and others. MANGET says that measles delays the suppuration of small-pox, when both coexist; and ETTMÜLLER states, what is very surprising if it be true, namely, that he saw a case in which the eruption of small-pox broke out on one side, and that of measles on the other side. — (*b.*) *Scarlet fever* has also been seen coexisting with variola, both distempers pursuing their regular courses, by JENSENIUS, MALFATTI, KRÜGELSTEIN, MARSON, BARNES, and DESSESSARZ. Dr. GREGORY informs me, that he has seen, at the Small-pox Hospital, many unequivocal cases of the concurrence of small-pox and scarlatina anginosa; and that variola and cow-pox may coexist, as HOLM and others have contended. DESSESSARZ, who has paid much attention to the coexistence of variola with other specific diseases, mentions this concurrence of variola with *syphilis* and with *hooping-cough*, this latter delaying the eruption of variola, according to his observation. When vaccina and variola coexist, they may both run their usual course, or the one or other be more or less modified in aspect and progress.

59. iii. VARIOLA IN THE PREGNANT AND PUERPERAL STATES AND IN THE FŒTUS. — When a pregnant woman is seized with small-pox, abortion or premature labour may or may not take place, and the disease may or may not be communicated by the mother to the fœtus. Much depends upon the mild or the severe character of the distemper. If the disease be not very severe, the mother may not abort, and the fœtus may not be infected; but if the distemper be severe, confluent, or malignant, abortion takes place, as in nearly all instances of other malignant or pestilential maladies; the fœtus being dead, and furnishing proofs of its having contracted the malady. The communication of variola to the *fœtus* has been observed by H. AUGENIUS, FERNELIUS, DERHAM, FORESTUS, MEAD, MAURICEAU, KITE, MORTIMER, WRIGHT, FLINDERS, WATSON, DIMSDALE, HUNTER, LYNN, TURNBULL, PEARSON, and HAYGARTH. Dr. GREGORY remarks, that it does not necessarily happen that a pregnant woman, taking small-pox, conveys the disease to the child; several instances to the contrary have occurred at the Small-pox Hospital. An opinion was entertained by Dr. MEAD (but erroneously), that where a woman undergoes small-pox without aborting, the infant would remain through life unsusceptible, having, in fact, passed through the disease in utero. Dr. JENNER has detailed two cases, which prove very satisfactorily that a fœtus in utero may contract small-pox, provided the mother be exposed to the contagion, although she herself does not take it. "An infant, born under these circumstances, sickened for the small-pox five days after birth, and twelve from exposure to contagion." (*Op. Cit*, p. 751.) In several collections fœtuses are preserved whose skins are covered with variolous eruptions. The earliest period of fœtal life at which Dr. GREGORY ever saw traces of variolous eruption is four months.*

---

* The following abstract is taken chiefly from the American edition of Dr. GREGORY's work on "*Eruptive Fevers.*" Dr. MITCHELL (*Amer. Jour. of Med. Science*, vol. vii., p. 555.) adduces the case of a mother, who bore the marks of small-pox, with which she was affected in childhood, and whose infant was born in an apparently healthy state, but exhibited symptoms of variola three days after birth, and nine days after birth the pustules were in a state of complete maturity. M. DENEUX (*Ibid.*, vol. xi., p. 499.) instances the case of a woman who had been vaccinated and never had small-pox, but who bore an infant covered at birth with confluent small-pox in the eleventh or twelfth day of the eruption. Dr. C. GUOLI (*Ibid*, vol. iv., *new series*, p. 485.) states, that a child was born in June, 1841, covered with pustules of

60. When a pregnant woman is seized with small-pox so severely as to place her life in jeopardy, she aborts, the fœtus being generally dead; and the mother very rarely recovers. The abortion probably favours this event, especially if it be attended by much sanguineous discharge; but this event has taken place with equal rapidity where this discharge has been most remarkably small, or altogether wanting, as in a case which I lately attended with Mr. BARNWELL. The same issue is observed in respect of other dangerous maladies, especially low fevers, scarlatina, measles, and the several malignant and pestilential distempers. When small-pox is caught shortly before delivery, so that the fœtus is born before the disease has proceeded its full course, the fœtus is generally infected, and the distemper assumes in the mother a most severe and complicated or confluent form, recovery seldom taking place. I have seen several cases of variola in the puerperal state, infection having taken place before confinement, but I have met with only one in which the disease presented a mild form.

61. iv. OF THE CHARACTERS OF THE LOCAL AFFECTION AND OF THE FEVER.—*A.* The *local changes*, whether external, as evinced by the varying condition of the eruption, or internal, and constituting the contingent complications of the malady, present every phase or gradation of inflammatory action, from the most slight to the most disorganising, from the sthenic to the most asthenic, or that most rapidly passing into the dissolution of structure.

62. *B.* The *type of fever*, whether of that ushering in the disease, or of that developing the suppuration or maturation, also varies in respect of power and vital resistance, — as respects the organic nervous energy and the states of the circulation and circulating fluids, — from that which may be viewed as inflammatory, until it sinks into the most malignant and pestilential, passing, in different cases, through every intermediate type, form, or phase; the local changes always presenting a more or less intimate relation to the state or character of the febrile commotion. Nevertheless, however numerous the forms or states, either of the local changes or of the constitutional disturbance, this distemper, more remarkably even than any other specific disease, preserves all its special properties unaltered and unalterable, elaborates the same poisonous miasm and virus, and propagates its kind through innumerable generations, without changing or even modifying any of its features. The same now as it was twelve centuries ago, it has lost none of its qualities or attributes, and gained no new property. We observe it now as it was observed from the earliest periods of its history; with the same remarkable modifications in both the local changes and the constitutional disturbance, the slightest and most benign form of morbid action, and the most pestilential; each form, and each intermediate phase appearing in the same epidemic, in the same locality, and in the same family, the distemper, nevertheless, preserving its special nature and identity.

63. The very remarkable modifications of variola now described are to be imputed — 1st., to vaccination; 2d., to inoculation; 3d., to infection by the mucous surfaces, and especially by the respiratory passages; 3d., to the dose or the quantity of the poison which has infected the frame, par-

---

variola. The pustules were at their height on the second day after birth, and maturated on the fifth; but the child died on the ninth day after birth. The mother had been vaccinated when an infant, and had escaped small-pox. M. GERARDIN (*Ibid.*, vol. vi., N. S., p. 210.) reported to the French Academy of Medicine, in 1842, an instance of a child born with the eruption in a state of suppuration; but no mention is made of the mother in this case. Dr. JOSLIN (*Ibid.*, vol. v., N. S., p. 249.) met with a case of small-pox in the fœtus, in New York, in 1842. The fœtus had on its body about 170 regularly-formed pustules, apparently such as they are from eight to ten days after the attack. The child lived only a quarter of an hour. The infection had been received by the mother just thirty days previous to the birth of the child. She was exposed but once to a single case, at the very commencement of the eruption, and for a single day. She had been vaccinated in early childhood, and the operation had been repeated on the day of exposure by Dr. JOSLIN himself, but without effect. M. DAPAUL (*Bullet. de Thérap.*, 30th April, 1849) saw a case of transmission of variola from a mother to her child, which had numerous pustules at birth. The mother had visited a person with the disease a short time before, without taking it. A case occurred in the Maternity Hospital, in Paris, in which the face, scalp, and different parts were covered with the pustules of small-pox at birth, though the mother retained the marks of vaccination, and had never had the small-pox. About ten days before, she had seen a patient at La Pitié, near another with small-pox (*Lancet*, 18th Feb., 1813, p. 741.). Dr. MEAD (*Works*, ch. iv., p. 253.) has recorded an instance in which a woman was delivered of a dead child at the full time, covered with variolous pustules. She formerly had the disease, and was attending her husband with it, when delivery took place. Dr. LEBERT (*Bullet. de Thérap.*, 30th April, 1849) exhibited to the Biological Society of Paris, a fœtus about four months old, whose body was covered with pustules of variola. The mother had the disease slightly, and aborted during her convalescence. Dr. KING (*New York Med. & Surg. Journ.*, April, 1840, p. 292.) mentions the birth of a living child at seven months, covered with umbilicated pustules, the mother having entirely recovered, and presenting at the time of its birth no evidences of the eruption, excepting the red spots succeeding the scabs; the child having been born twenty-one days after she was first attacked, or seventeen days after the appearance of the eruption. Dr. L. V. BELL (*Amer. Journ. of Med. Scien.*, May, 1836) adduces an instance of a lady who had confluent variola at the seventh month of pregnancy, and escaped without abortion, — a rare circumstance in confluent small-pox. At the expiration of her full term, she was delivered of a healthy child, whose abdomen and thighs were marked with decided small-pox pittings, and who was unsusceptible of the vaccine disease. VAN SWIETEN (*Commentaria*, vol. v., p. 8.) records, amongst several others, a similar case to the last; the child was born at the full time, with pits of small-pox, the disease having been transmitted to the fœtus through its mother, who had herself undergone the disease. Dr. HOSACK (*Med. Essays*, vol. ii., p. 111., & vol. iii., p. 473.) refers to numerous other instances, recorded by authors, of the communication of variola to the fœtus in utero.

"It will be found, on examination of the preceding and of other cases, that the communication of variola to the *fœtus in utero* has occurred after vaccination of the mother in infancy, and after her revaccination on the day of her exposure, and also after variola, both naturally and by inoculation. It has also taken place when the mother is yet suffering from the disease, and after she has passed through it years previously, and when she herself escapes entirely.

"The fœtus may be infected by absorption of the virus through the mother, without her experiencing any effect from it; or the disease may be transmitted directly by inoculation of the mother, and may be communicated any time from the fourth month (and perhaps earlier) to the full time. The fœtus may be thrown off in three or four days after cessation of motion, or may be retained for three or four weeks.

"The child may be covered with eruption at birth, and this eruption may present itself in different stages of its progress in different cases, even up to the eleventh or twelfth day of the eruption, or may not appear until three or four, or even seven days after birth. It may also be born at full time, with pits left by the disease some weeks previously."

The child either falls a victim to the disease at once, or lingers for only a few days; but it has been born healthy at the full time, with marks of previous disease; and it has survived when the disease, in a mild form, has appeared after birth. On this, and all other topics connected with variola, the admirable Commentaries of VAN SWIETEN on the Aphorisms of BOERHAAVE will be studied with advantage.

ticularly by these passages, relatively to the vital power and resistance of the patient; 4th, to the constitutional power, habit of body, diathesis, temperament, and health of the patient; 5th, to his race, or to the variety of his species; 6th, to his modes of living, mental power, and moral courage; 7th, to the physical agents which surround and influence him, especially the conditions of the atmosphere in respect of temperature and humidity, of purity and requisite renewal,—in short, to the various circumstances which I have pointed out, in full detail, when treating of the several causes and sources of pestilences, with reference to their removal and avoidance (*see art.* Pestilences, Protection from); and, 8th, to the character or nature of the prevailing epidemic constitution.

64. According to the influence of these, either singly or in various combinations, the disease assumes a mild, or a distinct, or a severe, or a semi-confluent, or a confluent, or a complicated, or a malignant form, the primary and consecutive fever developing these several states, or at least presenting, conformably with them, and with strict reference to them individually, either a slight, or mild, or an inflammatory, or an adynamic, or asthenic, or a putro-adynamic, or a malignant character, the appearance of the eruption being one of the chief indications of the type or character of the fever. Certain of the modifying influences now enumerated may require a brief remark. The first four mentioned manifestly need no comment.

65. The *race*, or the *variety of the species*, to which the patient belongs, is of the greatest importance in modifying the distemper. The white race, especially that inhabiting northern and temperate climates, experiences a much milder and, more frequently, a discrete form than the dark races, particularly the Negro. Amongst the latter races, the disease more commonly assumes a confluent or malignant form, and is the most dangerous pestilence which can overtake them. It is to them what the hæmogastric pestilence is to the Europeans when they migrate to the hot countries where and when that pestilence is epidemic. Amongst the dark races this pestilence is comparatively mild, but most fatal amongst the white race; whilst the very opposite obtains in respect of small-pox. As to this, I speak from personal observation. There is nothing which can be conceived more pestilential than I have seen small-pox when it has seized upon a Negro town or community: the general malignancy of the distemper, the desertion of the afflicted by the healthy who have not passed through the disease, and the semi-putrid or decomposed and hideous appearances of those who are yet alive, but nevertheless exhibit much of the characters of structural dissolution, cannot fail of making a never-to-be-forgotten impression on the observer.

66. The state of the atmosphere is also very influential in forming the general character of small-pox. In dry, pure, and moderately cold or cool states of the air, this distemper is much milder and less prevalent than in hot seasons, and in humid and still states of the atmosphere. In countries enjoying the former atmospheric conditions, the malady is less generally and severely epidemic than in warm countries, where the latter conditions obtain; there are, however, frequent exceptions to this law that probably are dependent upon the unknown nature of epidemic constitutions; but this topic, and others connected with it, will be considered more fully in the sequel. (§§ 93. *et seq.*)

67. The form or character of the malady thus depending upon the circumstances now mentioned, and modified as above described, must, in the present state of our knowledge, be viewed as the result of agencies which tend either to resist or to limit the susceptibility and the poisonous properties of the miasm or virus which produces it on the one hand, or to increase that susceptibility, or to develope the injurious operation of these poisonous properties on the other. We observe, 1st., that a previous attack, with very rare exceptions, destroys the susceptibility of a second infection; 2d., that vaccination produces a similar effect, but for a certain time only, at least in many instances; 3d., that the mode of communicating the malady, which is the best calculated to secure the introduction of the smallest possible quantity of the poison into the system capable of infecting it, is the safest and best, namely, inoculation; 4th, that whatever tends to promote the excreting functions, to depurate the blood, to resist the contamination of the fluids, and to support the vital powers, also favours the production of a mild or discrete form of the malady; 5th, whatever has a contrary tendency — whatever occasions contamination of the blood, as a foul, close, or frequently-respired air, and interruption of one or more of those functions, by means of which effete or injurious elements are eliminated from the blood — developes a severe, a complicated, or a confluent and malignant form of small-pox; and, 6th, whatever reduces vital power and resistance at the period of infection, and favours the reception of a large dose of the poisonous miasm into the lungs, as in cases of infection by respiring the morbid emanation directly or closely from the sick, relatively to the susceptibility of the individual, generally gives rise to the dangerous varieties of the distemper just mentioned.

68. v. Appearances on Dissection. — The changes which more especially belong to small-pox are those observed in the skin and mucous surfaces. Those of the skin require no remark. The rare exception, however, of death occurring either before the eruption has appeared, or at a later period, when the amount of internal disease, or the poisoned state of the blood, has prevented the evolution of the eruption, should be kept in recollection. The pharynx, larynx, and trachea generally display more or less disease, especially in cases which have proved fatal from the seventh to the tenth day. The mucous membrane of these parts appears covered with viscid, puriform matter, more or less copious, and of a brownish or greyish colour. Underneath this, the membrane is generally found congested, softened, thickened, and pulpy; and in the more malignant cases it is black and sloughy, and exhales an offensive odour. Congestion, softening, discolouration, &c., with a muco-puriform or sanguineo-puriform exudation, may often be traced down the trachea, and thence to the bronchial ramifications to a greater or less extent. The lungs frequently evince congestive or inflammatory appearances, or rather such changes as may be referred to a congestive pneumonia, or this associated with bronchitis, or an alteration approaching in appearance to that of

splenisation, with or without a puriform infiltration. The pleura is often inflamed, but it presents no changes different from those which are often seen in asthenic inflammations of serous membranes, occurring in the course of other exanthematous and adynamic fevers. As in these, so in this, the inflammatory affection is attended by injection, softening and thickening of the membrane, with an exudation of lymph forming a layer varying very much in thickness and density. These changes extend more or less to one or even to both sides; the cavity of the pleura also containing much sero-puriform fluid resembling a dirty whey, or a mixture of milk or cream and water.

69. It was believed by many that, in the dangerous states of small-pox, a pustular eruption took place in various portions of the digestive canal; and there can be no doubt of considerable alteration being observed in this quarter. These alterations may have assumed a papular or vesicular form, or one approaching the appearance of pustules, when the follicular glands of the digestive surface were chiefly inflamed. These changes have been remarked in the œsophagus, in the stomach, and in the small and large intestines. Dr. Gregory remarks, that "much discussion has taken place regarding the occurrence of variolous pustules on the gastro-enteric mucous membrane. Cotugno, Wrisberg, Reil, and others, who have paid great attention to the subject, concur in opinion that this structure is not capable of developing them. Sir G. Blane, again, reports a case where this membrane presented the appearance of ulcerated spots, which he compared to variolous pustules. The experience furnished by the Small-pox Hospital is in favour of the old doctrine. Inflamed, enlarged, and ulcerated follicles, with petechial patches, may indeed be noticed in a few cases; but such changes are in all respects the same with those observable in typhoid fevers." I have seen ecchymoses with or without those alterations, in the digestive mucous surface, and in the internal surface of the urinary bladder, but much more rarely in this latter situation. The kidneys are often congested, and the internal surface of the pelvis of the kidneys is also congested, softened, and discoloured. But these appearances, as well as those observed in the brain and its membranes, in the spleen, liver, and biliary organs, are very much the same as those seen in fatal cases of the other exanthemata, and of low or malignant fevers.

70. IV. Diagnosis of Small-pox.— It is not easy, and, indeed, seldom even possible, to distinguish the primary fever of variola from that of the other exanthemtaa, or even from the commencement of continued fever. In children, however, there is a more frequent occurrence of convulsions, more sudden and severe vomiting, and pain at the epigastrium, than in these; and in adults the muscular and other pains are more severe.—(*a.*) The fever of *measles* is more generally attended by cough and watering of the eyes than that of variola; and the eruption is about twenty-four hours later in the former than in the latter. The papulæ of small-pox are firmer and deeper seated than those of measles, which are superficial, and do not give so knobby or so granular a sensation to the touch as those of the former, which implicate the cutis vera.

71. (*b.*) *Febrile lichen* may be confounded with small-pox; but the interval between the occurrence of rigor and the appearance of eruption is much shorter in the former, generally only twenty-four hours, or half the time of that of the latter. The eruption of variola generally appears first on the face, whilst that of lichen takes place uniformly over the head and trunk, is superficial, and devoid of the granular feel to the touch which belongs to variola. (*See art.* Lichen.)

72. (*c.*) A form of *secondary syphilis* sometimes occurs, in which the eruption over the face and trunk is very similar to distinct small-pox, and passes through the grades of papulæ, vesicles, and pustules. It is, however, generally preceded by little, or by a slighter fever, and the eruption is much more tedious in its development than that of variola; the pustules do not maturate, or proceed simultaneously, but irregularly, or in successive crops. The general aspect of the patient, and the history of the case, will farther assist the diagnosis.

73. (*d.*) The diagnosis between *variola* and *varicella* has been fully discussed, and the distinct natures of these have been shown at another place; but independently of various other points of difference, the impossibility of inoculating the latter, the occurrence of it after cow-pox, and even after small-pox, and the absence from varicella of the deep-seated granular sensation to the touch, and of the umbilicated vesicle, characteristic of the variolous eruption, sufficiently distinguish the one from the other.* (*See art.* Chicken-pox, §§ 2, 3, 10, 11.)

---

* The following remarks respecting the distinct nature of *Chicken-pox* and *Small-pox*, contained in Dr. Gregory's excellent work, already referred to, deserve perusal, and quite agree with my own observation. "The first thing I observe in varicella is the eruption of vesicles of the size of a split pea, being simple elevations of the cuticle, or minute blisters. The parts chiefly occupied by the eruption are the back and scalp. The face is not so universally the seat of eruption as in variola; nevertheless, at times, the face is extensively occupied. The vesicles vary in shape; Dr. Willan, who loved minuteness, wishes to distinguish three kinds, — the lenticular, the conoidal, and globate. I cannot see these distinctions myself. The vesicles are surrounded by a superficial and narrow areola. They appear in successive crops for two or three days. While the new vesicles are forming, the old ones shrivel and dry up. On penetrating the vesicles, a clear lymph, scarcely at all mucilaginous, escapes, and the cuticle falls to the level of the surrounding skin. There is no tumour, no varus. If the vesicles remain unbroken for twenty-four hours, the contained fluid becomes slightly opaque. They are very itchy, and when rubbed, a degree of superficial inflammation may succeed, sufficient to convert the lymph into an imperfect pus. The scabs of varicella are very small, and as the lymph is wanting in mucilaginous quality, they are granular. The desiccation is very rapid, and in six days the complaint completes the whole cycle of its phases. No constitutional symptoms of much importance are present. The complaint often shows itself in schools, and runs through all the young members of a family. It is manifestly infectious and epidemic."

Varicella almost exclusively attacks children, it is very rarely seen in adults. "It is taken indiscriminately by those who have and those who have not been vaccinated. It is now nearly always taken *after* vaccination. Whether it was taken equally after inoculation of small-pox I cannot tell from my own experience, but I have the authority of the late Sir Henry Halford for saying that it was. These general considerations are of themselves sufficient to decide the question of non-identity. But if we examine the subject still more closely we find that the organization of the varicelloid vesicle differs from that of the variolous; there is no umbilication, no central depression, no slough. There is simply elevation of the cuticle, of irregular and undetermined arrangement. Here we see no groupings into threes, or fives, — no crescentic or circular figures formed. Everything in varicella is hurried forward — the incubation, the eruption, the desiccation."

74. V. **THE PROGNOSIS OF SMALL-POX** is tolerably manifest from what has been already stated. The circumstances enumerated above as modifying and aggravating the fever of small-pox (§§ 63. *et seq.*), increase also the *danger* of the distemper; but the following more especially tend to this: — 1st. The quantity and confluence of the eruption. 2d. The state of the circulating fluids. 3d. The presence and nature of the complications, especially those of the respiratory organs and nervous centres. 4th. The age, habit of body, and temperament of the patient. 5th. The circumstances and influences under which the patient is placed; and 6th. The season, temperature, and epidemic constitution in which the disease occurs.

75. *a.* A *confluent form* of the malady should, even when proceeding favourably, be viewed with distrust; for, in children, a fit of convulsion may occur, and carry off the patient; and in adults the blood may become contaminated to an extent incompatible with the continuance of life; or the secondary fever may further implicate vital parts. If the vesicles on the trunk and extremities be flat, with a claret-coloured or livid areola, "while the eruption on the face is white and pasty, no reasonable hope of recovery can be entertained." An excessive quantity of eruption always tends to depress vitality, to vitiate the blood, and to favour the occurrence of internal complications, which concur with these to destroy life. On the other hand, if the pustules on the extremities acuminate, and exhibit a crimson areola, a good ground of hope is furnished.

76. *b.* The *contamination of the fluids*, as shown by the hue of the surface, the colour of the lips, tongue, and gums, so far as they can show it; by the appearance of the vesicles; by the state of the evacuations; and by whatever indicates a tendency to putrescency, or a partially dissolved state of the blood and depressed organic nervous influence, is extremely dangerous. Petechiæ, ecchymosis, gangrenous, or sloughing, sores; hæmorrhages from mucous canals, the blood being dark, dissolved, or ichorous; menorrhagia, or hæmaturia; the vesicles being filled with a dark, bloody, or ichorous matter; purulent depositions in the joints, &c., are generally fatal indications.

77. *c.* The occurrence of any of the *pulmonary complications* mentioned above; cough or hoarseness at an early period of the disease; hæmoptysis at a more advanced stage; bronchitis, or congestive pneumonia, or asthenic pleuritis, especially when either extends to both sides, are extremely unfavourable. The appearance, also, of an abundant or confluent eruption in the puerperal states, and particularly soon after parturition, is always attended by the utmost danger.

78. *d.* The state of the *nervous system* is most important in the diagnosis. Continued delirium, or prolonged want of sleep, restlessness, moaning, despondency, or an inward persuasion of death, or an apathetic condition, or unconcern as to the result, so frequently observed in pestilential maladies, suppression of urine, sopor, lethargy or coma, leipothymia, or a tendency to faint upon raising the head from the pillow, or attempting to sit up, are severally dangerous or fatal symptoms.

79. *e.* The *age* of the patient is of much importance in the diagnosis, especially in confluent and semi-confluent cases. Dr. GREGORY remarks, that "the extremes of life are those on which small-pox always falls the heaviest. Persons above 40 years of age seldom recover even from the semi-confluent small-pox. Children are in danger from an amount of eruption that can scarcely be called semi-confluent. In both, the processes of maturation and cicatrisation are attended by great exhaustion of nervous power, the result of which is often the setting up of acute inflammation in an internal organ essential to life — either the brain, the larynx, or the lungs. The most favourable age for taking small-pox is from the seventh to the fourteenth year, when the powers of life and reproduction are in their fullest vigour."

80. *f.* The *habit of body and diathesis* have considerable influence on the result. A plethoric habit of body, a sanguine, a melancholic, a leucophlegmatic, or a bilious temperament, constitutional asthenia or debility, and a scrofulous diathesis, are more or less aggravating circumstances, as respects either the severity of the disease, and abundance or confluence of the eruption, or the complication and sequelæ of the malady.

81. *g.* The circumstances which indicate a *favourable issue* are, a discrete form of the disease

---

There is a form of Small-pox which, in some of its features, and from its mildness, may be mistaken for varicella; "and physicians in former times, looking only to the general, and neglecting the minute anatomical characters of the eruption, have thought proper to confound the two diseases. By way of distinction we will call the one *varicella vera;* the other, *variola varicelloides.* In the true varicella there is little or no premonitory fever. In the variola varicelloides there are at least forty-eight hours of preceding febrile disturbance. In the varicella vera there are no hard vari or tubercles. In the varicelloid form of variola, tuberculous elevations of the skin are distinctly perceptible. In the vesicles of the one there are no central depressions, in the other central depressions exist." In true varicella the crusts quickly fall off, and rarely leave any pits. Can varicella be communicated by inoculation? "Dr. WILLAN entertained the belief that it can; but his experiments are few (two or three only), and these few, to my mind, very unsatisfactory. Since his time, Mr. BRYCE, by more extended and more careful investigation, has set the question at rest. He states that he has inoculated with the fluid of varicella vera, at all periods of the disease, and at all seasons of the year, children who had never undergone either small-pox or cow-pox, and yet that he had never been successful in producing from it either variola or varicella. Since the date of BRYCE's experiments (1816), I know of none on the inoculation of varicella."

What, then, are the arguments which can be brought forward in support of the doctrine of the identity of small-pox and chicken-pox? I have adduced the arguments which have been urged by Dr. THOMSON, and others in favour of this doctrine, and I have answered them seriatim in another place (*see art.* CHICKEN-POX, §§ 2, 3. 10, 11.); but, nevertheless, it is interesting to know what further Dr. GREGORY has stated as to this topic. Dr. THOMSON's great argument is, "that varicella presents itself when variola prevails, and never without. Hence," says he, "we may deduce the probability that one contagion is operating, not two." The answer to this is, that the facts are incorrectly stated. Varicella frequently prevails without variola. Dr. MOHL has shown this most satisfactorily from the experience of the Copenhagen epidemics. From 1809 to 1823, Chicken-pox was annually observed at Copenhagen without accompanying variola; since 1823 both diseases have prevailed epidemically, but the physicians could always trace their sources, and this convinced them that the generating miasms were distinct. Besides, the doctrine goes for nothing if it can be shown, as has been shown over and over again, that some children take varicella after cow-pox, and others cow-pox after varicella, while sometimes both diseases may be seen going through their phases at the same time. "It cannot be doubted for one moment, after reading the details of this controversy in the works of Dr. THOMSON and elsewhere, that a very large proportion of the cases of alleged secondary or recurrent small-pox, are really cases of genuine lymphatic varicella mistaken for small-pox;" or, I may add, that the supposed first attack of variola was merely that of varicella.

the absence of any symptom of complication; a natural tone of the voice, and freedom from cough and hoarseness; an age between six and twenty-six; the occurrence of the malady at a cool, dry season, and under other favourable influences, as respects air, ventilation, and healthiness of position.

82. *h.* Much, however, depends upon the state of the patient before the accession of the malady, upon the influences in operation during the treatment, upon the measures which have been employed at the commencement of the distemper, or during its earlier stages; upon the purity of the air, and the ventilation of the patient's apartment; upon his nursing, and the noninterference of friends; upon the character of the prevailing epidemic, or of the reigning epidemic constitution; and upon various subordinate circumstances and unexpected contingencies.

83. VI. THE CAUSES OF DEATH from small-pox are, 1st., during the first week, or prior to the maturation of the eruption, the poisonous influence of the variolous miasm or virus on the blood, and the consecutive effects of the poison on the organic nerves and nervous centres; 2d., during the second week the greater number of deaths occur, and the most common cause is asphyxia, or consecutive vitiation, and interrupted oxidation of the blood, owing to the prominent affection of the respiratory passages, or of the lungs, or to suppression or interruption of the urinary excretion; 3d., during the third week, or when secondary fever has advanced, death may be produced by effusion on the brain, or by effusion in the pleura, or in the pericardium, or by the complications which occasion it in the second week; or by gangrenous destruction of some portion of the integuments; 4th, during the fourth, or following week, death may result from erysipelas, or from some other complication or sequela of the distemper. The following table, furnished by Dr. GREGORY, exhibits the days on which 168 cases of small-pox were fatal at the Small-pox Hospital in 1828–29, and proves that no importance can be attached to critical days in this distemper:—

Days.	Fatal Cases.	Days.	Fatal Cases.	Days.	Fatal Cases.

84. VII. CAUSES OF SMALL-POX. — i. From the earliest accounts of small-pox to the days of BOERHAAVE, variola was considered to owe its origin to the same causes, with certain unknown modifications, which give rise to other epidemic maladies, aided by infection and contagion. It was thus believed that small-pox might be generated *de novo*, from some defect or vice in one or more of the six non-naturals, — air, aliment, the secretions, exercise, sleep, and mental emotions, but that when thus produced it would spread by infection. BOERHAAVE was the first to contend that this doctrine was incorrect, and that small-pox was in all cases the product of a specific miasm or poison, derived from the same malady. "He acknowledged that the miasm must originally have sprung from some fortuitous combination of common causes, and that what had happened once might happen again, but he held that this contingency was improbable, and might safely be excluded from our reasonings."

85. It is impossible to say, with any degree of confidence, in what source, or in what combination of causes, or under what influences, the poisonous miasm first constituting and afterwards perpe-

---

[*] Nearly the whole of these 1753 cases were above the age of fifteen years.

[†] Many of the persons alleging to have been *vaccinated*, but not showing cicatrices, were doubtless duly vaccinated; but to distinguish such cases from the others was impossible.

[‡] N. B. The persons professing to have had small-pox at some former period, sometimes announced themselves to have been inoculated, sometimes to have had the casual small-pox, but in no one instance was there any corroborating evidence of the truth of the statement. These cases, therefore, are included in the third column of "*persons unprotected.*"

tuating the disease was produced. There is some reason, however, to infer, from what we know of the origin of certain distempers, and of the communicability of them from the lower animals to man, and from the proofs of the causes, and of this communication of these distempers, furnished by the old historians, as shown in the articles EPIDEMIC INFLUENCE (§§ 12. *et seq.*) and INFECTION (§§ 4. *et seq.*), and by modern pathological and other writers, that this malady, as well as they, originated in the lower animals, and extended from them to the human species by infection or contagion. However this may be, there is no proof that the disease appears or becomes epidemic, after longer or shorter intervals, owing to certain combinations of causes or influences, producing it *de novo*. On the contrary, there is every reason to infer, that it is perpetuated by its miasms, or effluvium, or virus, which spreads it by infecting the healthy, either directly, or indirectly by the media of substances — of *fomites* — which preserve, for longer or shorter periods, and thus propagate the poisonous agent (*see art.* INFECTION, §§ 16. *et seq.*); and that this distemper has been thus perpetuated since its first appearance in the 6th century. Instances are constantly occurring of either single cases, or of the outbreak of several or of many cases, without proofs of antecedent infection or contagion having been obtained, especially as respects the earliest cases. But as regards these, all the preceding circumstances or occurrences may not be known, or even may not admit of recognition; and as respects many of these, the same or similar circumstances may have taken place to those which occurred in the following case adduced by Dr. GREGORY:— A child took the small-pox, in the country, under circumstances which seemed to exclude all suspicion of infection. She had never left the house for several weeks; the few neighbours who had called were free from sickness, and no small-pox existed in the neighbourhood. During her convalescence, a looking-glass being put into her hands, she immediately said, "My face is exactly like that of the child at the door, from whom I bought the beads." On inquiry, it was found that some pedlars had passed through the village, and that the child had been to the door, although she had never left the house. Had this child died, or been an inattentive observer, the origin of this attack of variola must have remained for ever mysterious.

86. When we consider the facts connected with *infection*, as I have shown in that article, and the long periods during which the infectious miasm may be retained by fomites without losing its specific character and operation, and connect this with the numerous substances which may thus become the media of infection, and with the many occasions on which one or other of these media may have come within the sphere of our senses, without our recollection or knowledge, — and, moreover, when the long period which elapses from the moment of exposure to infection to the manifestation of the distemper is taken into account, the frequent difficulty or impossibility of accounting for the infection cannot be a matter of wonder. The poisonous miasm of small-pox is given out from all the mucous, cutaneous, and excreting surfaces,—especially the lungs and skin, — the exhalations, the secretions, the excretions, the matters in the vesicles and pustules, and the scabs, all contain this poisonous material, with all its specific characters; and this material attaches itself to many dissimilar substances, especially to the bed clothes, body clothes, woollen and cotton articles, &c. These when wrapped up, or in any way excluded from the free action of the air, retain the specific miasm for a very long but indeterminate time, and give out this miasm when opened up and exposed to the air.

87. The length of time during which fomites will retain the infectious miasm, with all its properties unimpaired, has not been ascertained; but there is reason to believe that, when they are excluded from the air, this miasm may be preserved for many months, or even for some years. The stages of the distemper during which the infectious emanation is most abundant and noxious, have been variously estimated, but without any accurate data. There is every reason to infer that the disease may be communicated by respiring the air containing the morbid effluvium from the commencement of the eruptive fever; and it may be admitted, that the infectious miasm is most powerful or concentrated when it is most manifest to the sense of smell. The dried crusts of the pustules, or scabs, not only also possess a contagious quality, but also retain this quality for a very long time, especially when shut up from the atmosphere, or undecomposed; and the dead body possesses also the power of infection, both by the effluvium which it exhales, and by the matter in the pustules. How long this power continues after death, has not been determined with precision, but it may last from a week to a fortnight, according to the exposure of the body to the air, and to the temperature and humidity of the atmosphere.

88. The distance at which the infectious property may be exerted, has been variously estimated by Dr. HAYGARTH and others. Some suppose that the sphere of infection does not extend further than a few feet, whilst others contend that it may extend to many hundred feet. An American physician informed Dr. HAYGARTH, that the infectious effluvium crossed a river 1500 feet wide, and affected ten out of twelve carpenters at work on the other side. The sphere of infection mainly depends upon the state of the atmosphere, and the existing epidemic constitution: a still, warm, humid, and impure air extending the sphere of infection; and a cool, dry, and pure air, and free ventilation, circumscribing this sphere, by diluting and dissipating the poisonous miasm.

89. It is obviously of importance to ascertain what degree of cold and heat, or what proportion or amount of chlorine gas, or of the chlorides in solution, is capable of destroying the poisonous miasm or virus contained in fomites, in order that these agents may be employed in disinfecting bed and body clothes; but our knowledge of the disinfecting powers of these agents, although considerable, requires much greater precision than it at present possesses. There is, however, sufficient reason to believe, that a temperature of about 200°, or somewhat above this range, is sufficient to destroy the infectious property, and that these chemical agents produce a similar result in moderately concentrated solutions.

90. During the last century, and even at the commencement of the present, a singular notion as

to the origin of small-pox, and as to the possibility of the entire extirpation of the distemper, was promulgated, and even entertained by some respectable writers, namely, that small-pox was generated *de novo* in infants by the blood of the mother left in the portion of the umbilical chord, attached to the fœtus on tying the chord—that the fluids remaining in this portion of the chord being absorbed by the fœtal vessels, thereby contaminated the blood and frame of the infant, and thus developed anew the distemper under consideration, independently of infection or contagion received from any other source. It was therefore recommended by these writers, in order to prevent the generation of the distemper, and ultimately to procure its entire extirpation, that the portion of the chord attached to the fœtus should be thoroughly emulged, and the fluids pressed out of it, upon securing it at delivery. That small-pox neither originated in this source, nor can be extirpated or prevented by any method of managing this operation, will not be disputed at the present day, however great importance may be attached to it in other respects.

91. ii. *The causes predisposing to, or increasing, the susceptibility of the infection of small-pox* are not wanting in importance.—*A. A very early age* has much influence in predisposing to this distemper. It has been admitted by Dr. HAYGARTH and other writers, that the greatest mortality by small-pox takes place in the early periods of life. In 1795 (before the introduction of vaccination), it was computed that, in Chester, nearly half the deaths among children below ten years of age was due to small-pox. From the data furnished by Mr. FARR's first and second reports, it appears that out of every hundred who died of small-pox in England, seventy-five were below the age of five years. Of 9,762 persons, who died of this disease in England, in 1837 and 1838, there were 7,340 under the age of five years; 1,668 between the ages of five and fifteen years; 528 between fifteen and thirty; 210 between thirty and seventy; and 16 upwards of seventy years of age. Of 2,285 persons who died of small-pox in London in 1840 and 1841, 2,060 were under fifteen years of age. During the last quarter of the last century (from 1775 to 1800), that is, prior to the discovery of vaccination, the proportion of the mortality by small-pox to the total mortality, was as 8 to 100 in London; and it was probably the same throughout the country. From the commencement of the present century, the proportion has varied much, rising in years when small-pox was prevalent, as in 1838, as high as this, and in other years falling far below it.

92. The susceptibility of infection exists in all persons who have not had the disease, and who have not been vaccinated, but in various degrees: it is greatest in infancy and childhood, and least in advanced age. Dr. GREGORY, however, thinks that this greater mortality from small-pox does not depend upon a greater susceptibility of infection, but because the disease is usually contracted on the first exposure to the infectious miasm. There can be no doubt of this being the case, but it is chiefly owing to the susceptibility being so remarkable at this age. Numerous exceptions have, however, been remarked to this general susceptibility. Both before and after the introduction of inoculation, many persons were frequently exposed to infection without experiencing the disease; and this circumstance, which is common to all infectious and pestilential maladies, was most ignorantly urged by non-contagionists as an argument against the existence of an infectious property; they either not adverting to, or concealing the fact, that many of those who thus appeared quite unsusceptible of infection, had the disease communicated to them by inoculation. "A lady, in 1804, was successfully inoculated for small-pox at the age of 83, and lived several years afterwards. She had brought up a large family, most of whom she had attended in attacks of small-pox, but had never taken it herself." I shall have to show in another place, that the susceptibility which, in vaccinated persons, is destroyed for some years, returns with advancing age, and becomes greater as life advances.

93. *B.* The several causes which predispose the system to the infection of other pestilential maladies, have a similar effect in spreading small-pox. Of these the most manifest are diathesis, or peculiarity of constitution; humid and warm seasons and states of the air; a close and stagnant or impure atmosphere; fear of infection; an endemic or epidemic constitution, favourable to the diffusion or operation of the poison; arrival from a pure and healthy air into a locality in which the malady is prevalent; and the constitution of the Negro and dark races.—*a.* A delicate conformation and susceptibility of the nervous system, a scrofulous or other diathesis existing in families, and exhaustion or depression by previous disease or other causes, either predispose the frame to infection, or render the malady more severe.—*b.* A high range of temperature*, especially when conjoined with humidity, stillness, and impurities, arising from animal or vegetable decomposition, both predispose the frames of those who are subjected to these causes, and concentrate the poisonous miasm emanating from the sick, and spread this miasm in a wider sphere.—*c.* Fear of being attacked, by depressing vital power, lays the body more open to the invasion, as in all other pestilential maladies.—*d.* There is something in the state of the stationary epidemic constitution which certainly influences variola and other epidemic distempers, and which we are unable to demonstrate otherwise than in the characters of its results; but although the epidemic prevalence of small-pox may be limited to a particular place, or extended over a whole country, either in cold seasons or weather, or in warm seasons and countries, yet it is most severely and generally prevalent in these latter circumstances.—*e.* The constitution of the dark races evinces a remarkable susceptibility of variolous infection. The destructive epidemics which have occurred in warm climates, and in the western world, il-

---

* BOERHAAVE, one of the ablest illustrators of the pathology of small-pox, states, "Est ut plurimum epidemicus, verno tempore primo incipiens, æstate crescens, languens autumno, hyeme sequente fere cedens, vere iterum eodem ordine rediturus." The truth of this was shown in the course of the Norwich epidemic of 1819, when a few cases only were observed in the preceding winter, and the greatest prevalence and mortality were in June and July. Small-pox was introduced also into the town of Lynn at the commencement of this year, but did not spread with rapidity until summer. A knowledge of this circumstance induces the native inoculators in the East to inoculate the small-pox in the cool season.

lustrate this fact. Although in many of these much may be attributed to the high range of temperature, humidity, and other concurring causes, nevertheless much more should be assigned to peculiarity of constitution, as evinced by the remarkable prevalence and fatality of the distemper when introduced into America among the natives of all climates and localities in that quarter of the globe.

94. C. There are certain circumstances, *apart from vaccination*, which influence not merely the susceptibility, but also the character of the malady. Those just mentioned (§§ 91. *et seq.*), whilst they increase the former, have generally a very remarkable influence in augmenting the quantity of the eruption and the severity and malignancy of the distemper. — *a.* The character of the case generating the infection has no influence upon that produced by it, whether the infection has taken place through the medium of the lungs, or by inoculation; a discrete case may occasion a confluent or malignant one, or this latter the former. This may arise from the susceptibility, or constitution, or diathesis of the infected, or from the quantity or concentration of the poison inhaled in a tainted atmosphere. The general mildness of the distemper, when inoculated, may be the result of the small quantity of the poison which may be administered in this way. — *b.* The best state of health, or vigor of constitution, may favour the occurrence of infection, but it will also favour the appearance of a mild form of the disease; whilst unhealthy or cachectic states of the frame, or some pre-existing disorder, may diminish the disposition to be attacked, and yet may render the distemper more severe or malignant when the infection is once produced. — *c.* Certain physical and other influences or circumstances may concur with the first manifestation of disorder to render variola mild, or discrete, or confluent, or malignant. Some of these, especially high temperature and impurity of the air, have been already noticed (§ 93.), as tending to aggravate the malady. Whatever determines the circulation to the surface, as warm baths, cordials, a heating regimen, too many bed-clothes, stimulating diaphoretics, a plethoric habit of body, and external irritants, increase the quantity, or favour the confluence, of the eruption; whilst a cool, dry air, large and well-ventilated apartments, a cooling regimen, and active purgatives taken during the latent period, or at the commencement of the primary fever, diminish the quantity of eruption, determine the circulation from the external surface and lower febrile action. Vascular plethora, especially if accompanied with more or less excrementitial accumulations, favour not merely a confluent or malignant form of the distemper, but many of the complications described above (§§ 44. *et seq.*). Extreme debility, weakness of constitution, and anæmia, delay the eruption, and impress the malady with a nervous or asthenic character.

95. F. *Epidemic visitations* of small-pox observe several of the same laws as govern the recurrence of other epidemic pestilences: — 1st. They return to a locality after a varying number of years, the intervening years presenting merely a few cases. This may, in some measure, be owing to the numbers of susceptible or unprotected cases having become, after many years, so numerous, as to furnish a sufficient supply to an epidemic outbreak; the straggling or few cases usually met with readily extending the infection to the accumulated mass of susceptible persons, as soon as states of air and other influences concur to predispose their constitutions to this result.

96. 2d. These visitations are characterised by greater severity, and are attended by a greater mortality, than when the disease occurs in solitary instances, or when it does not assume an epidemic prevalence: this may be owing to aërial or other causes having predisposed the constitution of susceptible or unprotected persons to severer attacks, and partly also to more concentrated states of the poisonous miasm conveyed by the air from the sick to the healthy. It is thus not uncommon to find persons who have been exposed to the infection of small-pox on ordinary occasions without being attacked, who nevertheless are seized by the disease in the severest form when it is epidemic.

97. 3d. Small-pox epidemics, like others, have a more or less gradual increase, and, when they reach their height, a gradual decrease. The rapidity of progress towards their height and their disappearance necessarily depend upon the population of districts where they break out, upon the numbers of susceptible persons, upon the communications, direct or indirect, between the sick and healthy, upon the observance of segregation, upon the rapidity with which the susceptible are infected, and upon the prevalence of the atmospheric, and other concurring influences to the formation of an epidemic constitution, either in a limited locality or in a more extended sphere.

98. 4th. Small-pox differs from other pestilences, inasmuch as that it may be propagated at all seasons of the year, and in very different atmospheric conditions, although with varying grades of rapidity and prevalence; whereas other infectious pestilences, as I have shown when treating of these, require certain ranges of temperature for their epidemic prevalence, or even for their contingent or possible communication. But small-pox, like scarlet fever and measles, although favoured more or less by temperature and season as these are, may prevail at any season in temperate countries, and more especially in the British Isles, yet the more general and most severe epidemics appear during warm seasons, or when a high temperature and much moisture in the air favour predisposition of constitution and the concentration of the poison. This compatibility of infection with any season and range of temperature incidental to temperate countries, accounts for the circumstance of small-pox, as well as scarlet fever and measles, being a domiciliated malady in these countries, although occurring after longer or shorter intervals in epidemic forms of prevalence and severity, as the numbers of unprotected persons become increased, or as the protection of vaccination wears out.

99. 5th. Epidemic small-pox may be local, owing to local circumstances and influences, as occurred in Norwich in 1819, when, between the months of May and October, about 530 persons died of the distemper within the limits of the bills of mortality, which do not include several parishes in the immediate neighbourhood, where it also prevailed. The limited occurrence of small-pox epidemics is often owing to the combination of morbid influences existing in the locality thus visited. In

Norwich and other places, as Edinburgh, Glasgow, Lynn, Liverpool, &c., where such epidemics appeared, many, if not all the elements of an epidemic constitution already existed, and favoured the spread of the distemper either from isolated cases, or from an introduced infection or fomites.

100. 6th. Not only may persons be seized with small-pox, during its epidemic prevalence, who had previously escaped, although exposed to infection (§§ 95. *et seq.*), but also persons who have been vaccinated, and who, after long periods, have been revaccinated, and even inoculated with small-pox, without effect, may on such an occasion be attacked by variola. This was observed by Mr. Crosse in the Norwich epidemic of 1819, when the protective influence of vaccination may be presumed to have been greater than now, a shorter period having elapsed in most cases since the process was adopted. The small-pox thus following vaccination, after periods of different durations, but generally upwards of seven or eight years, although more or less modified, and commonly modified in proportion to the shortness of the period which had elapsed from vaccination, cannot be mistaken for any other eruptive disease, for, independently of the character of the eruption, inoculation with the matter from the vesicles of the modified malady has produced regular small-pox in the unprotected, as was shown by Mr. Crosse and others. It is chiefly during small-pox epidemics that the protective influence of vaccination is tested, and it is then that the amount and duration of this protection, in connection with proofs of an efficient and healthy vaccination, can be duly estimated. (*See art.* Vaccination.)

101. 7th. As I demonstrated with respect to scarlet fever, when epidemic, that that malady sometimes presented a most dangerous form, in which there was no eruption, and sometimes even no sore throat (*see* Scarlet Fever, §§ 26. *et seq.*), so it has been observed that an analogous form of small-pox occurs in some severe epidemics, especially in places where all the elements of epidemic severity concur to produce great malignancy. Thus it is recorded by Mr. Crosse, in his history of the Norwich epidemic of 1819, that a number of cases of fever with petechiæ, but without any variolous eruption, appeared in May, June, and July, when the epidemic was at the worst, and all terminated fatally. The victims were mostly children, enfeebled by scrofula, or some other disease; and as several were thus seized, whilst others in the same family were suffering from small-pox, and as no case of this kind occurred in any one who had previously gone through small-pox, Mr. Crosse ascribed (and, in my opinion, very justly) every case of it to the variolous infection.

102. 8th. Before the introduction of inoculation into Europe, and when variola appeared only in its natural form, the epidemics of it which occasionally appeared, especially when the numbers of the unprotected, by a previous attack, became greatly increased, were often most destructive and pestilential. The outbreaks of small-pox in London in former times frequently carried off several thousand persons in a few months. In 1720, upwards of 20,000 persons were said to have died of it in Paris; and Horstius states that the epidemic visitations of variola "aliquandô adeô sævæ et malignæ sunt, ut instar veræ et legitimæ trucis pestis in omnem ætatem et sexum grassentur et fervirant cum multorum jacturâ et perditione;" and that, in 1614, it ravaged most of the countries of Europe more destructively than the plague, "in summâ nulli parcentes regioni, unius anni curriculo totam Europam seriatim visitârunt atque enormiter depopulârunt." It may readily be conceived that, when the distemper appeared in a district or city, after an absence of many years, when the greater number of the inhabitants were unprotected, its spread would be rapid and its ravages great. The mortality in the epidemics which occurred previously to the introduction of inoculation must have been very great, when we consider the efficient and concurrent elements of epidemic prevalence and fatality which every where existed in those times, and the nature of the treatment generally adopted. Even in recent times, the proportion of deaths to the number attacked by natural small-pox in several epidemic visitations of the distemper has varied from one in six to one in four.

103. 9th. *The possibility of persons being attacked by small-pox a second time* has been contended for by many, and doubted by others, as Mead, Heberden, Monro, De Haen, &c. De la Condamine estimated second attacks as one in ten thousand. Whilst admitting the possibility of a second attack, I doubt if its occurrence be even so frequent as here estimated. It is only when the disease is epidemic, and the exposure to the infectious miasm has been prolonged, or the poison has been concentrated in the respired air, that it may occur. Dr. Gregory states that very few persons ever present themselves at the Small-pox Hospital who have affirmed that they had previously undergone the disease; and of these few, but a very small fraction can stand the test of rigid scrutiny. In one of the last cases that occurred, the medical man who witnessed the first seizure had misgivings as to the true nature of the case. No instance is recorded of the same person having been admitted twice at the Small-pox Hospital. As to second attacks of variola, there are several sources of error. Sometimes the first attack is incorrectly reported, sometimes the second. The same medical man very rarely has seen both attacks. Chicken-pox is very frequently mistaken for variola, and even psora, ecthyma, and even pustular syphilis, have given origin to mistakes. The case of recurring variola which made the greatest noise was that of Louis XV., who died of small-pox in 1774, at the age of 64, after having, as it is alleged, undergone that disease casually in 1724, when 14 years of age. But the physicians who attended him in this first attack were not agreed as to its having been small-pox; and it was known that he was abroad and well six or seven days after the eruption was out, further evincing the non-variolous nature of the attack. I therefore agree with Dr. Gregory in believing that the primary disorder which his majesty had was varicella.

104. VIII. Of the Inoculation of Small-pox. — Inoculation having been abolished by Act of Parliament, and the end held in view having been more satisfactorily obtained, as generally supposed, by having recourse to vaccination, it may appear unnecessary to many to make inoculation of small-pox a topic of discussion at this time. Yet when all the evidence connected with

the comparative merits of inoculation and vaccination in temperate and warm climates, and in different races of the species, is duly considered, some notice of this still not unimportant topic should not be omitted. At the time of my writing this, just half a century has elapsed since the discovery and introduction of vaccination; and after a quarter of a century of most transcendental laudation of the measure, with merely occasional whisperings of doubt, and after another quarter of a century of reverberated encomiums from well-paid vaccination boards, raised with a view of overbearing the increasing murmurings of disbelief among those who observe and think for themselves, the middle of the 19th century finds the majority of the profession, in all latitudes and hemispheres, doubtful as to the preponderance of advantages, present and prospective, to be obtained either from inoculation or from vaccination. In 1823, I stated in the *London Medical Repository* (see the Refer., &c.), from evidence which had come before me in families which had suffered in numbers from small-pox, that the protection afforded by vaccination was impaired by years, and wore out in twelve or fourteen years, or in a longer or shorter time, according to diathesis, &c. — that vaccinated persons were liable to small-pox, in a more or less modified form, after some years, say nine or eleven; in a mild but distinct and fully developed form in from twelve to fifteen years, and to the usual states of the distemper, according to diathesis, to exposure to infection and epidemic prevalence, after this more advanced age. What was then predicted has since been so generally fulfilled, that revaccination has been adopted in many places, and has often failed, natural small-pox having notwithstanding appeared in the revaccinated, — both in those in whom the measure appeared to have succeeded, and in those in whom it failed.

105. Thus half a century has brought us to the position that we are doubtful which to prefer, — vaccination, with its present benefits and its future contingent dangers, or inoculation, with its possible present dangers and its future advantages. If there were no other considerations, but these which could be seriously raised in connection with the inoculation of variola, I should, for my own part, and after a due consideration of the subject in its various bearings, be at no loss which to select for those for whom I feel the interest connected with the nearest relationship; but there is the contingent and not improbable diffusion of the variolous poison to the unprotected by inoculation to be taken into account; and there is obedience also to the laws, which is the duty of every good citizen, and is strictly observed by every well-educated physician, although systematically disregarded and trespassed by pretenders and irregular medical practitioners. Another half century, the end of the 19th century, will, I fear, find the physician no longer in doubt as to which he will choose, even in this climate, as he no longer can be in doubt in India and other parts of the East, and as respects the dark races, unless he be influenced by authority and prejudice, — influences which are equally unworthy the high position in which his profession places him in the estimation of those whose opinions alone deserve respect and consideration.

106. *Inoculation of small-pox* is the artificial insertion, beneath the cuticle, or in a wound or puncture, or the application on an abraded surface, of a person not previously attacked by small-pox, of a minute portion of the virus formed in the vesicles or pustules of one labouring under the malady. By this mode of communicating the malady, the system is generally infected by the smallest quantity of the poison capable of producing this effect. In the East, inoculation has been practised successfully, and in a rational manner, from a remote period — as remote as the history of the disease carries us. The following arguments have been adduced in favour of it, and previously to the discovery of vaccination powerfully recommended it; and even now they should be calmly weighed against the advantages of vaccination, as far as these have been yet ascertained, and as they may be valued prospectively.

107. (*a.*) All persons not protected by an attack of small-pox are liable to be seized with this distemper at any period of life, in every circumstance in which they be placed, and on any occasion. It therefore behoves them to obtain this protection as early as may be consistent with a safe and efficient recourse to it. Now this protection was formerly inoculation; more recently, and at present, the only legal protection is vaccination. The former communicated a milder form of the same disease as a certain protection; the latter transmits an affection, of a slight and by no means dangerous nature in itself, which is somewhat similar in certain respects, and which has the virtue of preventing an attack of small-pox for some years, and of rendering such attack milder in grade, and modified in character, for an indefinite period; this protection, however, is not durable, but terminates after an indefinite number of years; in some instances entirely exhausting itself, and leaving those who may consider themselves protected open to either a mild and modified, or a confluent, severe, or even fatal attack of the malady.

108. (*b.*) The individual and collective evils resulting from the infection of natural small-pox, whether appearing in scattered or rare cases, or breaking out with pestilential prevalence, are well known. The history of small-pox epidemics, as observed in communities furnishing numbers of unprotected persons, sufficiently demonstrates the devastation which followed the entire want of any protecting power, before the introduction of inoculation into Europe. When this protection was introduced, its influence was manifest, not only in respect of the persons who had recourse to it, but also as regarded the community, in diminishing the frequency and fatality of epidemic small-pox, and in furnishing protected persons to attend upon the infected. Still there was a certain amount of evil connected with this mode of protection. The chance of communicating a dangerous or even fatal malady, and the contingent propagation, from the inoculated individual to the unprotected, of this disease, dismayed many, and furnished arguments in former times against having recourse to it. When weighed in connection with the fact, that some few entirely escape small-pox during their whole lives, although these were admitted to be very few, many were induced entirely to neglect this mode of protection, and, in more recent times, to adopt a

milder method, and one which appeared to the public and to the profession, until lately, equally efficacious and permanent.

109. The chief objections here urged against inoculation were partly specious and partly just. Inoculation practised by ignorant, unskilled, and unprofessional hands, in improper seasons, ages, and circumstances, or with a total disregard of the states of health of those subjected to it, may occasionally be followed by dangerous or even fatal results. Nevertheless it has been shown that, with all these drawbacks, and without the precautions, the science, and the care, which the educated physician can employ, the proportion of deaths amongst the inoculated does not rise above 5 in 1000. That inoculation would spread the distemper is certainly true when a few only resort to it; but even such diffusion would prevent the recurrence of those pestilential epidemics which follow the accumulations of a great number of unprotected in one locality, and would diffuse the disease in a milder form than when it occurs epidemically; for it has been fully proved that infection from the inoculated distemper generally does not communicate so severe or dangerous an attack as infection from a natural and epidemic case. Besides, if inoculation were generally adopted at a proper age, there could not possibly be the pabulum for an epidemic outbreak, and scarcely the occurrence of a natural case.

110. (*c.*) Against this admitted amount of unfavourable contingency, must be placed the firm confidence of protection, which inoculation furnished to all persons, in all climates, and to all races within the tropics, and to the dark varieties of the species. In these climates and races, vaccination (which the law has made to supersede inoculation) has been demonstrated to be inefficacious; but in all these circumstances, however diversified or opposite, inoculation has been found, and still is found, the most certain protection from the severer distemper and from epidemic outbreaks.*

111. (*d.*) Several *unfavourable contingencies have been urged against inoculation;* but certain of these need not be apprehended. That this measure may communicate a severe, a disfiguring, or even a fatal malady to a person who may entirely escape it if inoculation were not performed, must be admitted; but this argument was without weight before the introduction of vaccination, and now the advantages of the one mode of protection should only be weighed against the other with the view of adopting either of them, for the neglect of both is manifestly not merely improper but even criminal. It has been urged that inoculation may not only be followed by a dangerous attack, but that it may develope other maladies, especially severe affections of the eyes, terminating in blindness, and diseases of various organs; but these would more certainly follow the natural infection of small-pox, which, without either inoculation or vaccination, could very rarely be avoided. To these contingencies vaccination is certainly not liable; but it should not be overlooked that scrofula and tubercular formations are more frequently observed after vaccination than after inoculation (see *art.* Scrofula, &c., §§ 48, 49.). The risk of a second attack after the inoculated small-pox has been urged; but this risk hardly exceeds a possibility, and should not be taken into account; the risk of being attacked after vaccination, or even after revaccination, being infinitely greater, especially during adult and advanced age. (See *art.* Vaccination.)

112. (*e.*) It has been urged by Dr. Baron and others, who are the most determined supporters of vaccination, that " the practice of inoculation, the greatest improvement ever introduced in the treatment of small-pox, although beneficial to the person inoculated, has been detrimental to mankind in general. It has kept up a constant source of noxious infection, which has more than counterbalanced the advantages of individual security." (*Life of Jenner*, vol. i., p. 260.) This is true only to a certain extent; for if all were inoculated early in life (as by law might be enforced) there could be few or none liable to the natural infection and epidemic visitation of the malady; and according to the numbers unprotected would be the risk of such infection and visitation. Inoculation, although practised the most during the last half of the 18th century, was nevertheless as often neglected or put off, until it was too late to prevent the natural infection, and hence all reasoning respecting it became inconclusive, especially in local and other circumstances, respecting which the particulars were either imperfectly known or altogether unknown.

113. Sir G. Blane has endeavoured to show that the proportion which the mortality by small-pox in London bore to the general mortality increased during the last century from 78 to 94 per thousand; and that the diffusion of small-pox by inoculation was more strongly exemplified in the country than in London; since there are many places where small-pox was not known for twenty, thirty, and even forty years, in which at present scarcely an adult can be found who has not had it. These arguments are, however, more specious than solid. For, as respects London, the increase of population, the diminished prevalence of all other diseases, and the prevalence of epidemic small-pox, are not duly estimated. From 1711 to 1740, when there was no inoculation, the deaths by small-pox were 65,383; from 1741 to 1770, when inoculation was coming into use, the deaths were 63,308; and from 1771 to 1800, when inoculation was the most frequent, the deaths were 57,268. The increase of population during these periods should not be overlooked. As to the escape of many places for many years, upon which Sir G. Blane has laid so much stress, it should be known, that such places were always

---

* Between December 1849 and April 1850 inclusive, 76 cases of small-pox were admitted into the General Hospital, Calcutta. Of these 20 died. Of the 76 admitted, 66 had been vaccinated. Of the 66 vaccinated, 41 had good cicatrices, and 25 had cicatrices not so well marked. Of the total 76 cases, 30 were severe and confluent, 46 mild or modified. Of the 10 unprotected cases, 5 were severe and confluent — of whom 4 died — and 5 were mild. Of the remaining 25 confluent cases, after vaccination, 12 had good cicatrices, and 13 cicatrices not so well marked. Of those that had been vaccinated in early life, 16 died, of whom half bore good scars, and half had scars not well marked. Of the whole number, 65 were males, 11 females; 8 were children aged five years or under, of whom 1 died. Six of these children had been vaccinated. The mortality here stated as occurring from variola after vaccination — 16 out of 66, or 24 per cent.— is the highest upon record in any country, and must be attributed either to the malignity of the prevailing epidemic, to the climate and locality, or to the influence of race, — probably in part to all these.

visited at last, and without exception, by most destructive epidemics, the great number of the unprotected furnishing an abundant papulum for their malignant and fatal prevalence. It becomes, therefore, much preferable to have, even in these places, the regular adoption of inoculation by qualified persons, with even the highest rate of mortality consequent upon this measure, than the immunity of many years, with a mortality of 25 or 30 per cent, as recorded of these epidemics.

114. There can be no doubt that early in, and about the middle of, the last century, when inoculation was adopted only by a few, and even afterwards, when inoculation was very irregularly practised, and when many, even the majority in many places, were left without that protection, that it multiplied the sources of infection; but this was merely a powerful argument then for universal inoculation, as it is now for the adoption either of vaccination or of inoculation, if the latter were allowed by the legislature. On this subject, as will more fully appear when vaccination comes under consideration, writers have been partisans, rather than calm examiners of facts, as formerly or at present observed, and as faithful expositors of what may rationally be expected.

115. *There are a few rules requisite to the safe conduct of inoculation* that ought to be observed: — 1st. This measure should be employed for persons in good health — in those who are neither debilitated, nor plethoric, nor obviously scrofulous. Debilitated persons should previously be restored to health, and the plethoric reduced by moderate evacuations and active exercise. All the secretions and excretions ought to be natural and free; and wherever a cachectic state of system, or indications of visceral congestion or obstruction exist, inoculation ought not to be performed. 2d. It may safely be practised at any age from three months and upwards, but it should not be resorted to during pregnancy and the puerperal states, on account of danger to the mother and child; nor during lactation. 3d. It may be practised at all seasons in temperate countries, and in all climates. The preferable season is that which is moderately cool, and admits of due ventilation of the patient's apartment. In warm climates, the coolest season of the year should be selected; and this season has always been selected by native inoculators in the warm climates of the East, where inoculation has been adopted from early ages. 4th. Inoculation is successful, compared with the natural distemper, in all races and climates, but more especially in the dark races, and in tropical countries; for, although the proportion of deaths after inoculation may be higher in the dark than in the white races, the protection furnished by it is even greater in the former than in the latter, natural small-pox being so remarkably destructive in all dark races.

116. That variolous inoculation by unqualified persons ought to be prevented by legislative enactment cannot be disputed; but there are circumstances which may render recourse to it, under due precautions, a justifiable measure, especially the following:— 1st. When small-pox unexpectedly breaks out in a district, at a time when vaccine virus is not to be obtained. 2d. When persons who have been vaccinated in infancy are about to proceed to inter-tropical climates, and are likely to visit places where small-pox either prevails or recurs epidemically. 3d. Among the dark races, when they will not adopt vaccination, or when the vaccine virus is inefficient, either as respects its local effects, or its protective power. 4th. When persons are insusceptible of vaccination, from peculiarity of constitution, or some other cause.

117. In the present state of our knowledge as to the protection furnished by vaccination — believing that this measure will never be generally adopted, and that, if it were so adopted, it could never altogether banish small-pox, nor prove a complete or lasting preventive of variolous infection — it becomes doubtful whether or no the amount of benefit conferred by vaccination will hereafter prove greater than would be furnished by the general adoption of inoculation: as respects inter-tropical climates and the dark races, the candid inquirer into the merits of both will ere long, even if not now, declare for the latter. As inoculation is still practised in some countries, as it is still in many climates preferred to vaccination, and as it is the measure to which the majority of persons above forty years of age owe their protection from the natural distemper, the more important particulars connected with its performance require to be stated; and I cannot do this better than nearly in the words of Dr. GREGORY:—

118. *Inoculated small-pox.*—Inoculation is performed by introducing into the arm, at the insertion of the deltoid muscle, by means of a lancet, a minute portion of variolous matter. The thin lymph of a fifth-day vesicle is to be preferred to the well-concocted purulent matter of the eighth day, but both are efficient. One incision only is to be made. A minute orange-coloured spot is perceptible on the second day, by aid of the microscope: on the third or fourth day, a sensation of pricking is felt in the part. The punctured point is hard, and a minute vesicle, whose centre is depressed, may be observed, surmounting an inflamed base. On the fifth day, the vesicle is well developed, and the areola commences. On the sixth day, the patient feels stiffness in the axilla, with pain. The inoculated part has become a hard and inflamed phlegmon; the subjacent cellular tissue having become involved in the inflammatory action. On the evening of the seventh, or early on the eighth day, rigours, headache, a fit of syncope, vomiting, an offensive state of the breath, alternate heats and chills, languor, lassitude, or, in the child, a convulsive paroxysm, announce the setting in of fever. The constitution sympathises with the progress of the local disorder, and the virus has affected the whole system.

119. On the appearance of febrile symptoms, the inflammation of the *inoculated part* of the arm spreads rapidly. An areola of irregular shape is soon completed, which displays within it minute confluent vesicles. On the tenth day, the arm is hard, tense, shining, and very red. The pustule discharges copiously, and ulceration has evidently penetrated the depth of the corion.

120. On the eighth day, spots of variolous *eruption* begin to show themselves in various, and often in the most distant parts of the body. In the majority of cases, the eruption is distinct and moderate. Two hundred vesicles are counted a

full crop. Sometimes not more than two or three papulæ can be discovered, which perhaps shrivel and dry up, without going through the regular process of maturation. In other cases, the eruption is full and semi-confluent, passing through all the stages to maturation, and scabbing, and cicatrisation, with as much perfection as the casual disease can display. Between these extremes every possible variety may be observed. The truly confluent eruption, with affection of the mucous surfaces, is very rare, and that implication of the fluids and of the nervous system, which together constitute the extreme of variolous malignity, is nearly, if not entirely, unknown. Secondary fever, therefore, is not common, at least in any intensity.

121. IX. TREATMENT. — Small-pox being a specific disease, of a determinate course as respects both the eruption and the febrile phenomena characterising it, is less amenable to treatment than most other acute diseases. Nevertheless rationally-devised means exert considerable influence on the course of the distemper. In many cases, little or no interference on the part of the physician may be required, but something is always expected from him when his aid is called in, and it should, therefore, be clearly known what measures may be injurious and what beneficial. In severe cases, however, medical aid is always more or less requisite and advantageous, but to be the latter it should be based upon sound pathological views, and upon an accurate recognition of existing morbid states. Dr. GREGORY justly remarks, that "it is a melancholy reflection, but too true, that for many hundred years the efforts of physicians were rather exerted to thwart nature, and to add to the malignancy of the disease, than to aid her in her efforts. Blisters, heating alexipharmics, large bleedings, opiates, ointments, masks and lotions to prevent pitting, were the great measures formerly pursued, not one of which can be recommended." We may smile at the red bed-hangings, the red blankets and counterpane, the mulberry wine, the juice of pomegranates, prescribed for the malady by JOHN OF GADDESDEN; "but if either he or GORDONIUS or GILBERTUS were to rise from their graves, and inquire whether this is one whit worse than mesmerism, or at all more absurd than homœopathy or hydropathy, we should, I fear, look a little foolish. Let us, then, avoid the errors of our ancestors, without reproaching them."

122. Even in more recent times, and down to the days of SYDENHAM, or even to those of VAN SWIETEN and HEBERDEN, physicians have entertained very erroneous notions as to the powers of medicine in small-pox, and as to the intentions by which they should be guided. They imagined that certain drugs possessed the power of promoting the eruption, and not only of promoting it, but of procuring a favourable sort — a power, however, which was much more frequently injurious than beneficial; and, as far as it was manifested, much less rational and serviceable than the means employed for ages in the East in the treatment of small-pox. In this disease, we remark, as in several others, that the boasted powers of doctrinal science, when not fully advanced, are often more prejudicial than beneficial, especially when blindly adopted, and applied without the guidance of rational observation.

123. The treatment of small-pox should be directed with similar *intentions* to those recommended for the management of other fevers. Means should be employed, 1st, to moderate febrile phenomena, whenever they are severe or excessive; 2d, to prevent or remove local determinations or congestions of blood, or other concomitant affections or structural changes; and, 3d, to support the powers of life, whenever they are inordinately depressed or exhausted, by the influence of the morbid poison on the nervous and circulating systems. These *indications* should never be overlooked in any form, stage, or state of the malady. In the mild or distinct form, the active adoption of them may not be required; yet even in it, the occasions which may demand their due observance should carefully be watched for, and promptly met when observed.

124. *A. The primary or initiatory fever* may not be recognised as that of small-pox in cases occurring independently of inoculation, or without obvious sources of infection, and in these the treatment of this stage must be conducted according to the principles developed under the treatment of continued fever (see *art.* FEVER, §§ 126. *et seq.*). If, however, it be known, or strongly suspected, that the incipient disease is small-pox, the question arises, shall there be any difference in the treatment to be adopted from that usually employed in continued fever? But, as it is in continued fever, so it is in small-pox, the febrile action, the type and character of the fever, may vary from inflammatory to adynamic, or even putro-adynamic, and display in the latter, as I have shown in respect of the former, not merely either extreme of type, but every intermediate phase. The treatment of this period, therefore, must necessarily depend upon the states of the pulse and of the general phenomena, in connection with existing evidence of vital power; and upon the acumen and capability of the physician in recognising with precision these various and varying states, and in controlling or guiding them to a successful issue. As remarked by SYDENHAM, the fate of the patient depends upon the treatment of this stage, — that is, of the first three days of the disease.

125. The patient should be removed to a large and airy chamber, which ought to be darkened and well ventilated. He should be laid on a hair mattress, and be covered by a moderate quantity of bed-clothes, his head resting on a hair pillow, as being more cool than that in common use. The temperature of the room should be, according to the amount of febrile heat, from 55° to 65°, but preferably from 55° to 60°. If the disease be distinct, and the febrile symptoms not very severe, the patient may not be confined to bed during the day, his clothing being appropriate to the circumstances in which he is placed. A dose of calomel with James's powder, or antimonial powder, should be given, and be followed, three hours afterwards, by a purgative pill or draught. After these, saline draughts in a state of effervescence may be prescribed from time to time, and the bowels preserved in a moderately open state by the usual cooling aperients. In the slighter forms of the disease, no further medicine will be required; the beverages, diet, and regimen of the patient being regulated as stated hereafter.

126. If the primary fever assume a more severe

and inflammatory character, and if the pain in the head, epigastrium, and loins, be too severe to be allayed by the above means, and more especially if the patient be robust or plethoric, blood should be taken from the arm, in such quantity as the peculiarities of the case may warrant, in addition to these means. When the brain, lungs, or liver is congested, or the pulse full, hard, oppressed, or sharp, a moderate bloodletting, relatively to the state of the patient, ought to be prescribed; and this measure will be still more requisite when the headache is intense, the face flushed, and the vessels throbbing, the irritability of stomach extreme, the breathing oppressed, and the pulse full and labouring. When the eyes are suffused, and headache is experienced, leeches applied to the temples, or behind the ears, may be sufficient; or, in the more phlogistic cases, they may be employed in aid of bleeding from the arm, and be followed by calomel, James's powder, a purgative draught or pill, and cooling draughts. Dr. GREGORY remarks, that "it has often been said that bloodletting, in the fever of invasion, interrupts the process of nature, repels the eruption, or so retards it, and so weakens the constitution, that the due concoction of the pustules is never effected. It is undeniable that a man may be bled unnecessarily and too largely in small-pox, but a moderate bleeding does no harm, and, if the fever runs high, often does great good." The propriety of having recourse to venesection, especially in the circumstances just mentioned, has been insisted on by SYDENHAM, BIENDISANT, TORRINI, DOVER, BERGER, STUBBES, FALCONET, and many others. DE VALDES recommended bloodletting nearly a century before SYDENHAM; and HECQUET advised bloodletting from the feet at this stage. HUFELAND very properly directed leeches to be applied to the temples when the disease was attended by convulsions. The quantity of blood to be drawn should depend upon the state of the pulse and other peculiarities of the case, always keeping in recollection the character of the prevailing epidemic and of physical influences.

127. *a. Emetics* have been advised by some writers on the invasion of the primary form of small-pox, and condemned by others. The propriety of having recourse to them depends upon the peculiarities of the case, the character of the epidemic and the season in which the distemper occurs. SYDENHAM prescribed an emetic, after bloodletting, in the primary fever, and in the secondary fever with internal complication. He likewise had recourse to it as soon as the disease appeared to be confluent. But there appears to have been much vacillation in his opinions as to both emetics and bloodletting in small-pox at different epochs of his practice, or rather during the different epidemic prevalences of the malady, as shown by his brief accounts of several epidemics; and I cannot depend so firmly upon the opinions of a physician, as many are disposed to do, who did not perceive, or duly estimate, the contagious and infectious nature of the malady. That emetics are often of service, especially at the commencement of the primary fever, and when indications of biliary obstruction, congestion, or accumulations are present, and during autumn or summer, I cannot doubt; but it requires close observation and experience to determine with precision the exact circumstances and period of the malady requiring their exhibition. They have been recommended by DEDEKIND, HECQUET, LEAKE, and many others, but in a too empirical manner, and with little regard to either the peculiarities of the case, the stage of the malady, or the choice of the agent. A writer in the Berlin Medical Transactions advises repeated emetics in this disease. The effects of one, however, will show the propriety of having recourse to it, and likewise of repeating it. In the low, adynamic, or confluent states of the disease, more especially, the choice of the agent is of some importance; for in these states, the more nauseating or depressing emetics, as tartar emetic or ipecacuanha, are not so appropriate as in the sthenic forms of the malady, unless they be conjoined with stimulants, aromatics, &c. In the former states the sulphate of zinc should be preferred. Some writers suppose that emetics diminish, others that they increase, the quantity of eruption; but it may be said of emetics, as of bloodletting, that they have little or no effect upon the eruption, or in lessening confluence. Their influence is exerted chiefly in promoting the excreting functions, whilst bloodletting diminishes inordinate vascular action, and relieves internal oppression and congestion.

128. *b. Purgatives* are generally beneficial during the primary fever, and very often also in the secondary fever; but they are required more especially when the secretions and excretions have not been duly evacuated previously to treatment, when the indications of local determinations, particularly to the head, are manifest, and when sthenic febrile excitement is considerable. In these circumstances, not only purgatives, but the whole of the *antiphlogistic regimen*, as insisted on by SYDENHAM, HOFFMANN, VAN SWIETEN, BARTHOLINUS, DIMSDALE, CURRIE, EYEREL, BEDDOES, PERKINS, &c., are beneficial. Much, however, depends upon the selection and combination of these means appropriately to the peculiarities of the case. In the primary fever, *calomel* is generally most serviceable, especially when conjoined with antimonials in the more sthenic forms of the disease, and with camphor in the more asthenic; but in most cases, a full dose of the calomel should be followed by a purgative draught in a few hours, if it have not operated sufficiently. Dr. FOWLER supposed that, when calomel was given early in the eruptive fever, it diminished the quantity of eruption. But it cannot have this effect, unless it be taken before the first indications of eruption exist, and then its influence must be necessarily doubtful.

129. OSIANDER very justly cautions against too much purging; for it may develope an intestinal complication, in the form of either diarrhœa or dysentery, and thereby greatly endanger the patient. In the more inflammatory or sthenic cases, the phosphate of soda, the citrate of magnesia, or other cooling saline purgatives, should be preferred, or such as may be compatible with the use of saline diaphoretics, as the liquor ammoniæ acetatis and spiritus ætheris nitrici; but in asthenic or confluent states of the disease, after a dose of calomel or camphor, I have preferred to give the spiritus terebinthinæ, with about an equal part of castor oil, on the surface of a suitable vehicle, in quantity sufficient to act moderately on the bowels. If this dose be rejected, the

effect will, notwithstanding, be more or less beneficial, and after some hours it should be repeated, or the same substances in larger doses should be administered in an enema, which may be repeated according to circumstances.

130. During the primary fever, pain at the epigastrium is often considerable, or even urgent, and is frequently accompanied with irritability of stomach, and the rejection of whatever is swallowed. It may be requisite, from the severity of these symptoms, to endeavour to abate them. This object will be most readily attained by giving a full dose of calomel with a moderate dose of camphor and opium, and a little cinnamon or ginger, in the form of bolus, or in that of powder mixed in a little treacle. In these circumstances, saline effervescing draughts, with or without tincture of opium, generally fail of giving relief. If the disease presenting these symptoms is of an asthenic or confluent kind, as commonly observed, or if the medicine now recommended is not sufficiently efficacious, a mustard poultice may be applied over the epigastrium, or a mustard pediluvium or semicupium may be employed. In most cases I have preferred, to the mustard poultice, the application over the epigastrium of equal parts of the compound camphor liniment and of the turpentine liniment, with a little cajuput oil, and sometimes with a little olive or almond oil, on the surface of flannel or spongio-piline.

131. *c. Cooling diaphoretics*, especially small or moderate doses of the solution of the acetate of ammonia, or of the citrate of ammonia, or of the citrate of magnesia, or of the citrate of soda or potass, with the spirit of nitric ether, according to the states of the surface and of the bowels, will generally be of service; and the acid may be somewhat in excess when vascular action is inordinate. Cold sponging the surface, during the early part of the primary fever, or even the cold affusion, may be resorted to, as advised by Bartholin, Currie, Beddoes, Jackson, and others; but when the eruption appears, these should be relinquished, for I believe that the recommendation of Schaeffer, Swainson, Hufeland, Watson and Selle not to employ these means at this period is altogether judicious. Marcard considered, and with much reason, that the tepid bath, previously to the appearance of the eruption, moderated the primary fever; and he recommended warm stimulating baths in the low and retrocedent states of the distemper. Many of the writers already named cautioned against carrying the cooling regimen too far, or employing excessive cold, in the treatment of low, confluent, or epidemic states of the disease, justly contending that a moderately cool or fresh state of the air, and a judicious recourse to restoratives or tonics were altogether indispensable in many cases, and especially in the epidemic prevalences of the malady. The treatment which appears the most appropriate to these cases will be hereafter stated (§§ 143. *et seq.*).

132. Dr. Gregory justly remarks, that "if the circulation at this period (the primary fever) be languid; if the pulse be small and feeble, the skin pale, and the extremities cold; if the patient lies on his back, sunk and exhausted, let him have immediately warm brandy and water, cover him with bed-clothes, apply mustard poultices to the centre and extremities of the circulating system, and give thirty drops of laudanum, to be repeated in four hours if necessary. This cordial plan of treatment must often be continued for several days, when the eruptive nisus is accompanied with depression, and nature appears so obviously unequal to the effort." (*Op. cit.*, p. 100.) In these circumstances, the opium should be given with camphor or ammonia, or both; and the hot terebinthinate epithem will generally be more efficacious than the mustard poultices.

133. *B.* During the progress of the eruption, and in the *remission of the fever* which produced it, but little beyond a suitable regimen is required. A too officious recourse to medicine is oftener prejudicial than the contrary. The same remark applies to the secondary fever, or suppurative stage, when the disease is discrete and there is no complication. During the period of eruption and development, however, the secretions and excretions should be carefully watched and cautiously promoted, without producing irritation; and the senses and mind ought to be guarded against excitement, very light and bland beverages, and mild, weak, farinaceous nourishment, in small quantity only, being allowed. Dr. Gregory's remarks as to the treatment of this stage are so judicious, that I shall adduce them at this place.

134. "While the pustules are in process of maturation, a variety of measures may be pursued, which, without interrupting the salutary and necessary process of pustulation, lessen the patient's sufferings, and prevent subsequent difficulties. If the eruption proceeds favourably, you would not do more than lessen thirst by saline draughts, and occasionally relieve the bowels by a dose of castor oil. If the maturation of a large crop of pustules excites much fever, it will be prudent to employ more active purgatives, such as calomel with colocynth, the compound powder of jalap, or the infusion of senna with salts, all which cause a drain from the blood-vessels and lower arterial action. Place the patient in a large and cool room, and cover him lightly with bed-clothes. Remove all flannel coverings which may usually be worn next the skin. If the surface be very tender, apply to it some cooling lotion, such as the decoction of bran with some spirit of rosemary. In all cases, even of moderate intensity, it is proper to cut the hair close, and so to maintain it during the whole course of the disease. The head is thus kept cool; delirium is relieved or prevented; the risk of cellular inflammation of the scalp diminished, cleanliness enforced, and an opportunity afforded for the employment of evaporating lotions, should more urgent symptoms arise. Opiates may be occasionally administered at bed-time, when there is much cuticular irritation, or great distress from want of sleep.

135. "The diet of the patient should consist of tea, bread and milk, arrowroot, rice-milk, and roasted apples. Grapes, oranges, and ripe subacid fruits are grateful to the patient, and useful adjuvants to the antiphlogistic remedies. Lemonade, apple-water, tamarind-water, toast-water, and milk-and-water, must be the ordinary beverages. Sydenham permitted his patients to drink small-beer — an indulgence which may still be granted. To that able physician we are indebted for this, the cooling system of treatment in small-pox.

136. "One of the first objects, which, in cases of more urgency, will attract your attention, is the condition of the throat. Gargles of infusum

rosæ comp. afford some relief. When the difficulty of swallowing is very great, and the tonsils much swollen, leeches applied to the throat, followed by poppy-water fomentations, are serviceable. Under these circumstances, some physicians counsel you to apply to the throat, by means of a camel-hair pencil, a strong solution of lunar caustic (twelve grains to the ounce), with the view of checking the advance of the mucous vesicles. I have not adopted this practice, from a conviction that it would not affect the tracheal inflammation, from which alone danger is to be apprehended." (*Op. cit.*, p. 101.) More recently, much stronger solutions of nitrate of silver — from forty to sixty grains to an ounce of distilled water — have been applied to the pharynx, inside of the glottis, and even within the larynx and upper part of the trachea, by means of a sponge attached to whalebone; and, it is said, with success in some cases. Chlorinated lotions and gargles are generally of use when the affection of the throat and nasal passages is severe in confluent small-pox.

137. *C.* During the *secondary fever*, when it is severe or complicated, the treatment should be active but discriminating. The use of *purgatives* at this period was once a question of warm discussion. Dr. GREGORY remarks as follows:— "One of the most remarkable disputes which ever arose in physic was that regarding the propriety of using purgatives during the secondary fever of small-pox. SYDENHAM, with all his boldness, never wholly divested himself of the early prejudices which the Arabians had inculcated against purgatives in small-pox. MORTON inveighed bitterly against their use, while Dr. FRIEND, with the true spirit of a reformer, advocated their free employment, especially during the secondary fever." "They are now as freely employed in the secondary fever of small-pox as in ague or in typhus. They are of the greatest service when the skin is hot and dry, when a scarlatinal rash covers the body, or innumerable abscesses give evidence of the excited state of the cutaneous vessels."

138. Agreeing with the foregoing remarks, I would add only that, when too strong, or too frequently exhibited, purgatives may induce a dangerous diarrhœa or dysentery, or an enteric complication, especially if the selection of the means be not sufficiently discriminating in respect of the peculiarities of the case. As long as the disease manifests but little exhaustion of vital power, this care may be of less importance; but when vascular action is asthenic, and constitutional power is depressed, then such aperients as promote excretion, and, at the same time, impart tone or energy, should be preferred. Such are the means advised above (§§ 128, 129.), and such also are the compound decoction of aloes, or the compound infusions of gentian and senna, given in conjunction with the carbonates of the alkalies and aromatic tinctures, or with the citrate of magnesia, or with the carbonate or citrate of ammonia. In many cases, it may be requisite to aid the operation of these by means of enemata containing the substances already mentioned, with such others as the exigencies of the case will suggest.

139. The propriety of *bloodletting* in the secondary fever has been denied by most writers, and contended for by others, but by these latter under certain circumstances only. SYDENHAM, when he first wrote on small-pox, advised bloodletting in the secondary fever of the confluent disease alternately with purging; but at later periods of his practice, and when describing the epidemics of 1670 and subsequent years, which were manifestly of a most malignant character, the treatment recommended by him was of a very different kind (§§ 147, 149.) from that formerly directed. It would seem that the small-pox previously to 1665 and 1666, that is, before the great plague, was of a more sthenic nature than subsequently; and that, after this most fatal epidemic, by which about 100,000 bodies were buried in a few months within and immediately around London, thus furnishing additional sources of contamination to both air and water for many years afterwards, small-pox and other febrile diseases presented a more malignant character, and required different means of cure from those formerly employed.

140. When the pulse presents more or less tone, and vascular action is high, in connection with internal complication — congestive or inflammatory — then bloodletting, cautiously and moderately employed, according to the peculiarities of the case, and aided by such means as may derive the fluids from the seat of complication, and promote excretion, &c., will prove of much service. But if the pulse be weak, very quick, compressible, or small and soft, and, more especially, if there appear any signs of putro-adynamia or malignancy, as respects either the state of the eruption or the constitutional symptoms, decided means of an opposite kind are obviously indicated (§§ 143. *et seq.*).

141. In the secondary fever, when uncomplicated with any *internal affection*, or *contamination* of the circulating fluids, little beyond the preservation of a free state of the secretions and excretions need be attempted; aided, however, by a suitable regimen. In cases presenting prominent affection either of the brain or its membranes, or of the lungs, pleura, &c., general or local bloodletting, or both, according to the peculiarities of each case, is generally requisite; and purgatives and derivatives are further required. The state of the surface may appear to contra-indicate a recourse to blisters; but when the pustules on the trunk, or in the situation where it is desirable to apply a blister, are few, then they may be applied; and in these circumstances, as well as in others in which they should not be resorted to, the terebinthinate embrocations or epithems, often recommended in this work, may be employed without regard to the state of pustulation in the situation, to which it may be desirable to make these applications. The treatment recommended in the complications of continued fevers (*see art.* FEVER, §§ 529. *et seq.*) is generally suitable to those which occur in the course of small-pox; existing pathological states furnishing the only true therapeutical indications in all forms of fever, whether simply continued, or exanthematous, or malignant.

142. Ophthalmia is one of the most common of the concomitant affections in small-pox. In many cases of this complication, the state of the system will not admit of general or copious bloodletting; but in these, as well as in most other severe cases, scarification of the conjunctiva, leeches or cupping-glasses on the temples, warm fomentations,

calomel, purgatives, terebinthinate medicines given by the mouth and in enemata, are required, and should be mainly depended on, in connection with such other internal, constitutional, or febrifuge means as the character and state of the febrile symptoms will suggest.

143. *D. In the confluent states of variola*, or even when the pustulation is profuse and general, the treatment should be such, from the commencement, as will not reduce the powers of life; and even before the eruption appears, and when the character of the primary fever, and the severity of the vomiting and pain in the back and loins, and the stinging heat of the surface, indicate a severe or confluent form of the disease, it may be necessary, especially if the pulse be very rapid, or deficient in tone, or broad, open, and very compressible, to have recourse to the more tonic of the several febrifuge medicines usually employed. In these cases, as well as in others presenting signs of putro-adynamia, as petechiæ, hæmorrhage from mucous canals, a dark brown or black appearance of the eruption, whether at an early stage, or during the maturation and secondary fever, the preparations of *cinchona*, either with the mineral acids or with the alkalies, according to the features of individual cases, are generally required.

144. Cinchona was prescribed in these states of the disease, in various forms of preparation and combination, and was administered in enemata by GESNER, FOUQUET, BAYLEY, HIRZEL, WALL, BALDINGER, and others; and they relied upon it chiefly in the secondary fever, when accompanied with sinking of the powers of life, or with putro-adynamia. HUFELAND advised the preparations of cinchona to be given with antimonial wine; but this combination is admissible only at an early stage of confluent or malignant cases, and is not suited to the more advanced stages, or when hæmorrhagic exudations are observed. In these latter circumstances, I have found the decoction of bark to be most beneficial when conjoined with the hydrochloric acid and the hydrochloric ether, or with the chlorate or the nitrate of potash and tincture of serpentaria, or with the nitric acid and spirit of nitric ether. The sulphuric acid was advised, in the form and states of the disease now being considered, by SYDENHAM, BROCKLESBY, WALDSMIDT, NOWACH, and others, conjoined with various stimulants. More recent writers have conjoined the decoction or infusion of cinchona with the sulphuric acid, and the spirits of sulphuric ether, for these and similar states of the distemper; and still more recent authors have employed the sulphate of quina in these or similar forms of combination. These means are severally of more or less service; and it may be even necessary to combine them still further, as with the tincture of opium, or with the compound tincture of camphor.

145. The nitric acid was recommended by Dr. SCOTT for the more adynamic and confluent states of the malady; the hydrochloric acid by JAHN, and the acetic acid with camphor by MARX, THOMANN, PLINTA, and HOPF. Either of these acids, or of those above mentioned (§§ 143, 144,), or the citric acid, is more or less beneficial when suitably conjoined with tonics, cordials, or stimulants, according to the peculiarities of the case; and in these combinations they have been prescribed by FALCONET, RUSH, THUESSINCK, LAFONTAINE, and others. Of the good effects of the acetic or the citric acid, conjoined with camphor, or with ammonia, this latter being in excess, and given with the infusion or decoction of cinchona, and aided, in the more severe cases, by wine, beef-tea, &c., I can speak from experience.

146. *E.* In the *petechial form* of small-pox, treatment will generally prove inefficacious. Dr. GREGORY thinks that it admits of no essential relief from medicine. He considers purgatives to be inadmissible, and mercury without influence. The loss of a little blood from the arm has appeared to him more effectual than any other measure. "The citrate of ammonia in effervescence, with port wine or brandy, may be given when the powers of life appear to fail, but the hæmorrhagic diathesis is often accompanied by a hot skin and an excited circulation." (*Op. cit.*, p. 104.) When the skin is hot and the circulation excited, in connection with petechiæ, or spots of purpura, or with hæmorrhage from mucous canals, the abstraction of a little blood from the arm may prove beneficial; but these symptoms should not prevent a recourse to the means just recommended (§§ 143. *et seq.*); for they often subside after a decided recourse to these means, especially when the medicines are directed to the prevention or counteraction of the contamination of the blood, and the defect of vital power, upon which they depend. When the prostration is not great, nor the hæmorrhage very considerable, nor the eruption of a dark or malignant hue, then recovery may follow a recourse to cinchona, conjoined with the chlorate or nitrate of potash, and with the carbonate of soda and cordial or stimulant tinctures; camphor, or small doses of turpentine, being given occasionally in the intervals between the exhibition of these. Instead of cinchona, the preparations of valerian may be employed. I have generally preferred them when delirium was present. If the bowels are affected, the preparations of opium, or the compound tincture of camphor, should be added to these; and if the evacuations are very offensive, as well as too frequent, pure charcoal-powder, or the chlorides in small but frequent doses, may be prescribed. When, with these putro-adynamic symptoms, the liver is inactive or congested, then the nitro-hydrochloric acids may be prescribed in the decoction or infusion of cinchona, or the infusion of valerian; and when cerebral symptoms predominate, or when low delirium, tremor, and nervous exhaustion prevail, then the tincture of *sumbul*, lately introduced into practice by Mr. SAVORY, will be found of great service.

147. In cases presenting more or less contamination of the circulation and adynamia, as those now considered usually present, small and repeated doses of *opium*, especially when conjoined with camphor, or the chlorides, or the nitro-hydrochloric acids, or with cinchona, or valerian, or sumbul, will generally be most serviceable. When the bowels are most relaxed, in such cases the preparations of opium are more especially required; and they may be given with milk and lime-water, or with aërated lime-water. In the circumstances just named, and more especially in the secondary fever attended by marked putro-adynamia or malignancy, WANDT and STROEM prescribed opium with the sulphate of alumina. Dr. DRUMMOND recommended the preparations of opium, in large doses, from the com-

mencement of the eruption in confluent cases; TRALLES, GEBEL and YOUNG adopted a similar treatment. P. FRANK considered these preparations to be deserving of our chief reliance in these cases; and the same opinion was entertained by HUXHAM, DE HAEN, HUFELAND, SPRENGEL, STOERCK, and others. SYDENHAM considered them of greatest service when exhibited on the fourth day of the eruption in adults, and given in the evening or towards night. He trusted to them especially in the confluent form, and about the eleventh day, or most dangerous period of the disease. THOMANN prescribed opiates in severe cases, after the exhibition of an emetic; and QUENTIN combined them with the oxide of zinc. The preparations of opium, with the exception of the weak paregoric of the pharmacopœia, cannot be given, without the risk of producing severe cerebral symptoms, in children under the age of four or five years; and even at that age, these symptoms may occur, if they be not guarded against by resorting to cold-sponging over the scalp, and by cooling aperients. In cases which most require opium, camphor, or ammonia, or the usual aromatics or stimulants, are also beneficial, and both promote the good effects, and counteract the injurious influence, of this substance. The excellent effects of the laudanum prescribed by SYDENHAM depended upon the combination of aromatics in its preparation — a combination which has been very imperfectly estimated, even by his warmest admirers.

148. *F.* The *laryngeal* and *tracheal affection*, arising in the course of severe variola, is generally an extension of the specific inflammation existing in the mouth and throat, and is seldom much ameliorated by the means already noticed (§§ 143 — 147.). After having had recourse to these, emetics, especially the sulphate of zinc, or ipecacuanha conjoined with camphor, or ammonia, or capsicum, may be tried; for these have a more decided effect upon the respiratory surfaces than is generally recognised, especially in removing the viscid mucus from the trachea and large bronchi that generally collects in large quantity in these situations when the severe forms of small-pox are thus complicated. In these complications, the decoction of senega, or the preparations of squill, or of ammoniacum, conjoined with camphor, or ammonia, or other substances which the circumstances of the case will suggest, may be prescribed; and if these expectorants should act as emetics, as they will generally act when given in large doses, the effect will be the more beneficial, especially in confluent, or severe, or malignant cases.

149. *G.* The occurrence of *diarrhœa* or of *dysenteric symptoms*, especially in connection with the secondary fever and in confluent cases, requires means which should partly depend upon the appearance of the evacuations. In most cases, the medicines already mentioned (§§ 146. *et seq.*), ipecacuanha with camphor and opium, or with powdered carbon and the compound chalk-powder; and the other medicines usually given for diarrhœa or dysentery, may be severally prescribed in these complications of small-pox. SYDENHAM gave boiled milk with lime-water in these cases, or with ammonia or magnesia when the stools evinced a somewhat sourish odour; and ROYER and many others adopted a similar practice. But when this complication appears in malignant, or even in the more usual confluent cases, more active astringents are required, and these should be associated with antiseptics, and absorbents, and opiates.

150. *H.* The state of the *urinary secretion* should receive due attention from an early period of the disease. The urine is often not only small in quantity, but also voided at long intervals in some instances; and it is occasionally remarkably high-coloured, and even contains albumen, and not infrequently blood, especially in the confluent and malignant cases. In the early stages of the more phlogistic cases, especially when the urine is scanty and very high-coloured, demulcents and diluents should be freely given, with the cooling diaphoretics already mentioned (§ 131.), and with diuretics of a cooling and febrifuge kind, as recommended by THOMANN, LENTIN, and others. When the urine contains albumen, or blood, globules, or even pure blood, then the terebinthinate embrocation or epithem may be applied over the loins, and repeated according to its effects.

151. *I. Small-pox in puerperal females*, especially when it occurs very soon after delivery, is always a most dangerous disease. Not only is it generally confluent, and attended by marked asthenia, but it is also complicated with very severe, and usually fatal, affection of the respiratory mucous surface, extending to both lungs. Of several cases of variola to which I have been called in the puerperal state, I have seen only one which was mild and uncomplicated. The treatment in these unfavourable circumstances should partly depend upon the time which has elapsed between delivery and the appearance of the distemper, partly upon the amount of hæmorrhage which has taken place at the period of delivery or subsequently, and upon the states of the lochia and of the lacteal secretion. When the discharges have been and are free, and the pulse is very frequent and soft, the severity of the laryngeal, bronchial, or pulmonary complication, or indeed of any other associated affection, should not prevent recourse to the means already recommended for the severe, confluent, and adynamic states of the malady (§§ 143. *et seq.*), especially to camphor, ammonia, wine, or other stimulants and tonics; or to such as are advised for the malignant form of *puerperal fever* (see that article). When the respiratory passages are very severely implicated, the remedies already mentioned, especially senega, squills, ammoniacum, sulphate of zinc, &c., prescribed as expectorants or as emetics, according to the emergency of the case, ought not then to be overlooked. The great severity and unfavourable prognosis of small-pox in the puerperal state should not prevent a decided recourse to the most active means in the treatment of this class of cases, but, on the contrary, should induce us to employ the most energetic medicines in the most prompt and appropriate manner.

152. ii. EXTERNAL MEANS HAVE BEEN USED TO GIVE RELIEF AND PREVENT PITTING, but they do not always succeed as respects the former intention, and they often fail as regards the latter. When pustulation is profuse, Dr. GREGORY advises the surface to be liberally covered with some simple dry powder. Starch-powder, hair-powder, and powdered calamine are alike available for this purpose; cold cream, and mild unguents,

such as the unguent. cetacei, with a proportion of oxide of bismuth, are useful when there is much cutaneous irritation with a dry surface. "Fomentations and poultices are the only means of treating those abscesses and erythematous inflammations which so harass the patient, and so fearfully peril life in the later periods of secondary fever. All the attempts made by the use of masks to prevent pitting end in disappointment. The only effectual means of lessening such disfigurement are those which allay cutaneous action. Purgative medicines, low diet, and free exposure of the face to a cool air, are the sole measures on which reliance should be placed." (*Op. cit.*, p. 108.)

153. Whilst these means ought to be adopted, others may also be tried. Fresh air should be duly admitted; but, at the same time, light ought to be excluded as completely as possible. I believe, from what I have observed in several cases, that complete darkness prevents pitting, and that light increases the suppurative action in the pustules, and thereby occasions deep and permanent marks. Whilst the patient should breathe a freely-renewed air, the vesicles should be protected from the action which the oxygen of the air exerts upon them; and this may be done by various means, either by causing the vesicles to discharge their contents before suppuration commences, and by favouring the drying of their contents upon their surfaces, the scabs thus forming a natural protection from the action of the air; or by covering the vesicles with some substance, which may lessen the suppurative process, by protecting them from the air, and by lowering inflammatory action in the cutaneous surface.

154. The Arabians opened the pustules as fast as they ripened by a gold needle; and the moderns have applied lunar caustic to the pustules, so as to destroy them at an early period of their development. As to this latter practice, Dr. Gregory remarks that, as a partial application — say to vesicles forming near the eye — he can recommend this measure; but that he cannot advise it to be employed to any large surface covered with confluent or semi-confluent vesicles. He adds, "The latest mode of treating the surface during the maturative stage of small-pox, is that of applying mercurial plasters, containing calomel, or corrosive muriate of mercury, or covering the whole surface with mercurial ointment. In the French hospitals at the present time, the latter mode is in fashion. The reports of its success are not, however, very flattering. I have seen all three plans fairly tried at the Small-pox Hospital. The ointment and calomel plasters were inefficient. The plaster of corrosive sublimate converted a mass of confluent vesicles into one painful and extensive blister; but I am still to learn what benefit the patient derived from the change." (*Op. cit.*, p. 103.)

155. Other means have been used for the prevention of pitting, either by causing the abortion of the pustules in the course of their development, or by drying them up after they have maturated. Dr. Bulkley remarks, that, as a general rule, the more recent the eruption, the more easily it is arrested. One writer thinks that the pustules can be arrested, even after their suppuration, and another fixes the period at which this can be done as late as the seventh day. In 1825, I tried the effect of complete exclusion of light in preventing pitting, and in that case it was altogether successful. I have since had recourse to it in three or four cases with success; in one confluent case it failed. I have, in three other cases, covered the surface of the face with almond or olive oil, and excluded light, keeping the apartment freely ventilated; these have not been marked; the eruption was very copious, but not confluent in any of these. Instead of almond or olive oil, glycerine, or collodion, as suggested by Dr. Ranking, may be employed.

156. Incising or opening the pustules, or rather the vesicles, as recommended by the Arabians, was the method of causing their abortion advised by Roggert, Voigt, Tournay, and Hufeland. M. Velpeau and Dr. Morton assert, that if the pustules are cauterised within two or three days, or even later, no marks will be left. The latter says that, if the face be frequently wetted with spirits of hartshorn, the inflammation will be abated, and the pustules will be prevented from becoming either large or irritable. M. Piorry recommends blisters to cause abortion of the pustules, but I consider their use not required in discrete cases, and of very equivocal benefit in the more severe states of the distemper. M. Malapert prescribes a solution of hydrate of potassa, which, he says, dries up the pustules, without leaving either cicatrices or stains. The strength of the solution is not stated.

157. Many years ago, Digby directed the face to be covered with *gold-leaf*. Larrey advised the same means, and stated that this method of preventing pitting by small-pox was employed from time immemorial by the Egyptians and Arabians. It can act only by excluding light and air from the diseased surface. Drs. Crawford and S. Jackson, of the United States, say that they have found the *tincture of iodine* to succeed in preventing the marks of variolous pustules; and various kinds of ointment and plaster have been also confidently recommended with this intention.

158. *Sulphuric ointment*, rubbed lightly, three times a day, over the parts affected, has been recommended for the prevention of suppuration in the pustules and the consequent pitting (*Gaz. Méd. de Paris*, Avril, 1841, p. 232.). The emplastrum plumbi, melted with oil of almonds, and laid over the face by a camel's-hair pencil, has been prescribed by Dr. Corrigan (*Dublin Quarterly Journ. of Med. Science*, Aug. 1846, p. 245.). A mask, composed of mercurial *ointment*, rendered more consistent by means of starch or fecula, is employed by M. Briquet. He causes it to be spread over the face, and to be renewed once or twice daily. He says that it produces abortion of the pustules, and prevents the swelling attending the confluent form of variola. The same means have been recommended by Prof. Bennett, of Edinburgh (*Edin. Monthly Journal of Med. Science*, Jan. 1850.).

159. A compound mercurial *plaster*, called the "plaster of Vigo," is often employed for the prevention of pitting by French physicians. According to M. Briquet, if mercurial plaster be applied before the fifth day of the eruption, one of two things happens — either the pustules disappear by resolution, or they are changed into vesicles or into tubercles. The latter change is more rare, and seldom takes place except on the face. When

the dressing is removed, small, hard excrescences, insensible to the touch, are seen, which gradually fade, and disappear at the end of ten or twelve days, partly by resolution and partly by desquamation, and without leaving any trace. The mercurial plaster must be kept on from eight to twelve days. (*Gaz. Méd. de Paris*, Avr. 1846.)

160. A solution of corrosive sublimate — one grain to seven ounces of distilled water, and a drachm of laudanum—applied by compresses kept wet with it, is also said by Dr. BULKLEY to produce very marked effects in causing the disappearance of pustules, even after they have fully matured; and he adds that simple mercurial ointment is much more frequently used, both in Europe and in America, than either the plasters of Vigo or the wash of the bichloride, and is probably equally efficacious. It may be applied freely with a brush, or a camel's-hair pencil. Dr. STEWARDSON, of Philadelphia, speaks very favourably of its effects (*Amer. Journ. of Med. Science*, June, 1843. *See also* Dr. BULKLEY's *Notes to* Dr. GREGORY's *Lect. on Erupt. Fevers.* New York. Ed. 1851, p. 351.).

161. iii. INOCULATED SMALL-POX should be treated according to the principles already insisted on, and with strict reference to the type or character of the primary fever, and other features of individual cases. The SUTTONS and DIMSDALE, whose reputation for successful inoculation became so remarkable about the middle of the last century, and somewhat later, insisted upon exposure of the surface of the body to cold air during the primary fever, and upon the full adoption of the antiphlogistic regimen.

162. It was recommended by many physicians who practised inoculation before the introduction of vaccination, to *prepare* the patient by treatment shortly before and after the operation, or until the primary fever appeared. Others considered any preparation unnecessary, and sometimes even prejudicial. Several eminent writers, such as THOMANN, HUFELAND, and others, advocated the propriety of correcting the secretions and excretions, and of promoting a free state of the several emunctories, especially when these appeared to require this aid, by one or more doses of calomel and antimony. FORDYCE, however, considered this practice to be unnecessary, and EYEREL, BOEHMER, and others contended that there is no mode of preparation of any use. GMELIN recommended abstinence from animal food for some time previously to inoculation, but WEIKARD believed even this plan to be injurious. On this topic, Dr. GREGORY very judiciously remarks, "Perfect health being the best condition for receiving and safely eliminating the poison, every thing that tends to diminish plethora, to lessen cutaneous action, to render the bowels free, to preserve the blood in a cool, pure, and normal condition, was found useful. Laxative medicines, a moderate diet, abstinence from all fermented and spirituous liquors, cool chambers, gentle exercise in the open air, light clothing, all contributed, in their several degrees, to the successful result. The antimonial and mercurial medicines, which the SUTTONS laid much stress upon, were useful only to secure the co-operation of the patient in matters of more necessity, especially diet and exposure to the open air." (*Op. cit.*, p. 110.)

SOFTENING OF STRUCTURE.

— SYNON: *Softness of organs*; — *Mollities*; — Μαλακότης (from μαλακός, mollis); — *Structuræ mollities*; — *μαχακοσαρκος*, Galen; — *Ramollissement*, Fr.; — *Erweichung, malacia*, Germ.

CLASSIF.: — GENERAL PATHOLOGY — MORBID STRUCTURE — THERAPEUTICS.

1. *An individual structure, or part, or organ, may present more or less softness, or diminution of its healthy or normal density, or of its natural state of vital cohesion*; — it may be preternaturally soft, still retaining its usual amount of cohesion; it may be unusually friable, without being softened, or without losing its density; but these states are comparatively rare, for when the one property is impaired the other is also diminished, and *with softening cohesion is generally proportionately lessened*. Softness of structure is commonly not merely physical, but also vital. The structure evinces an impaired cohesion of its molecules, and a diminished vital resistance to external agents. When treating of the changes evinced by individual structures, I have always described, as one of these changes, diminution of their cohesion, or softening. Thus softening of the brain, *Mollities cerebri*, is considered in the article BRAIN; softening of the heart, *Cardiomalacia*, in that on the HEART; softening of the stomach, *Gastromalacia*, in that on the STOMACH, &c.

2. I. PATHOLOGY OF SOFTENING OF STRUCTURE. — *Preternatural softness of structure* is sometimes recognised during life; but most frequently comes under the observation of the physician after the dissolution of his patient; and it then becomes sometimes a question how far it may be a post-mortem change. There can be no doubt of much of the softness often found in the brain or spinal cord after death is post-mortem, although the change may have commenced some time before death; and this remark equally applies to softening of the tissues of the *digestive canal*. (See this art., §§ 34. *et seq.*)

3. *Softening of structure may occur after death.* — 1st. From the action of the gastric juice on parts with which this fluid is brought in contact soon after, or at the time of dissolution. — 2d. From infiltration or maceration of effused fluids, and putrefaction.

4. Softening may take place *during life*. — 1st. From congestion, and, still more manifestly, from effusion or infiltration of blood in the structure. — 2d. From inflammatory action. — 3d. From disease of the arteries or veins connected with the softened part. — 4th. From impaired organic nervous power of the part, causing impaired nutrition, sometimes with serous infiltration, or with fatty degeneration, or with a certain amount of either of these. Softening of structure after death has been noticed when treating of changes observed in the digestive canal and in other organs; but I shall here offer a few remarks on the pathological conditions of which it is a consequence during life.

5. i. The several changes just enumerated as most frequently producing softening of structure are chiefly concerned in causing this effect in particular organs or parts. But there are other states which occasion a *more or less general softening or loss of vital cohesion in most of the structures of the body*; and this softening may exist in a very remarkable degree throughout the whole frame, excepting the bones. It is presented to us during life chiefly in pestilential diseases and malignant fevers, and occasionally as a result of virulent poisons. The softening of the structures in these distempers is a consequence, as I have shown when treating of these distempers, 1st., of impaired and vitiated organic nervous influence; — 2d., of a contaminated state of the blood, with an impaired crasis of its fibrine, and change of the blood-globules; these two prime factors of ulterior alteration acting and reacting on each other. The softening of structure in the more severe cases of the several pestilences, and in the more malignant of exanthematous and continued fevers, had been in great measure overlooked until I described it in early parts of this work and in other places; and to what I have advanced respecting these diseases, under their several heads, I must refer the reader for my description of this remarkable change — this general diminution of vital cohesion of the tissues — at an advanced stage of the malady, or towards the close of life, with the rapid accession of putrefaction after death. This general and rapid form of softening may be called *acute general softening of the tissues*, to distinguish it from *partial or limited softening*, on the one hand, and from *chronic general softening* on the other.

6. ii. When softening of structure is *partial as to its seat*, or *limited to a single structure or organ*, it is a consequence of one or more of the pathological states enumerated above (§ 4.). — *A.* It may be the result, or the concomitant, of *congestion of blood* in the capillaries of the part, or of an *exudation of blood* from these vessels, and of the infiltration of it in the substance of the part. When the vital or the organic nervous influence of the part, and of its vessels, is impaired, the blood is liable to congestion in the vessels, or to further change; and, as a consequence, or as a concomitant of this state, softening of the part is liable to supervene. If, as a result of this change in the capillaries and their contents, blood be effused into the structure of the part, softening still more certainly ensues, and with a rapidity proportionate to the failure of vital power and resistance in the surrounding parts. The softening which is observed in congested and enlarged spleen, whether occurring primarily, or as a consequence of periodic fevers, and some of the cases of softening of the lungs are illustrations of the consequences, or of

the concomitant effects, of congestion of a simple or asthenic kind; whilst the red softenings seen in portions of the brain, and the softening with ecchymoses and bloody infiltrations, observed in several viscera and structures in scurvy, purpura, asthenic hæmorrhages, and in malignant or putro-adynamic fevers, &c., show the great extent to which softening proceeds when it is accompanied with exudations of blood. In all cases, when blood is exuded, infiltrated through the structure, or accumulated in masses, and retained even for a short time, softening of an inflammatory kind, although asthenic as to tone, certainly supervenes, and extends, more or less, according to the grade of vital resistance.

7. *B. Inflammatory action* is generally attended by softening of the affected parts; and when softening has not become apparent, or even when the part seems more dense, owing to the infiltration of a concrescible lymph, there is a defect of vital cohesion, as evinced by increased friability. The sthenic and chronic states of inflammation evince less softening and friability than the more asthenic and acute states. Erysipelas and other spreading inflammations, and still more the diffusive inflammation of cellular and adipose tissues, are often attended by softening, amounting to diffluence and disorganisation; and in proof of these changes, I have only to refer to these maladies, and to the art. Gangrene.

8. *C. Disease of the arteries and veins*, especially of the former class of bloodvessels, is a very common cause of limited softening of organs. Obliteration of an artery, or even specific deposits in the coats, or other changes affecting the calibre, or impairing the healthy action of the vessel, as atheromatous or fatty deposits, may impair the nutrition of the part supplied by the diseased vessel, and thereby occasion softening and impaired vital cohesion of it. Instances of this connection or sequence, or even sometimes concomitance, of alteration, are often presented in the brain, heart, and other parts. Softening in these cases, more especially in the heart, is sometimes associated with a fatty degeneration of the structure of the organ. (See the chapter, in the article Heart, *on fatty degeneration of its structure*, §§ 224. *et seq.*) I have stated, when treating of *apoplexy*, that the change in the vessels of the brain, and in those of the heart, are sometimes the same at advanced age; and that whether the change be specific deposits in, or atheromatous or fatty degeneration of, the coats of the vessels, they frequently exist in the vessels of both these organs, and account for the not infrequent complication of disease of the heart with either apoplexy or palsy.

9. When the change in the arteries consists of atheromatous deposits in their coats, — which deposits were described by me in 1830, when writing on the diseases of arteries, and were stated to "consist of a suety matter, greasy to the touch," &c. (*see art.* Arteries, § 59.), — then the structures supplied by arteries thus affected are often not merely softened, but also otherwise changed; the softened part being flabby, and as if infiltrated with serum, and with more or less oil-globules. In other cases, especially when this change in the arteries is connected with softening of the cerebral structure, serous effusion often accompanies it, especially into the adjoining ventricles, and occasionally as an infiltration of the softened structure; this effusion being probably the result of the physical condition of the organ, and either of the state of circulation in the part, or in its vicinity, or of the atrophy sometimes attending softening. Whether or no softening of the cerebral structure is attended by more or less of fatty degeneration, as observed in the heart, has not been ascertained; but it is not improbable that the fatty elements, contributing in their various degrees, to produce what has been recently, and not always correctly, described as fat (and of which the earliest notices are contained in various articles of this work, especially Arteries, § 59.; Disease, §§ 135. *et seq.*; Heart, Structural Changes of, §§ 224. *et seq.*; Pleura, § 100.; Serous Membranes), are more or less augmented above the natural standard in the softened structure of the brain; the healthy structure of the organ containing from three to eight per cent. of fat, which exists chiefly in the medullary structure.

10. Disease of, or obstructed circulation through the *veins*, produces softening of the tissues, the blood of which passes to the affected veins; but the softening generally presents peculiar characters. It is always attended by great congestion, or infiltration of serum, or ecchymoses, or by all three. The vital tone or cohesion of tissues thus circumstanced is already partially lost; and when they are subjected to any irritation, inflammatory action of an asthenic character, is soon produced, which rapidly spreads, still further softens the part, and ultimately destroys its cohesion and organisation.

11. *D. The organic nervous influence* of a part is more or less impaired, either previous to, or in connection with, the changes already noticed as productive of softening. But this influence may be impaired primarily, and chiefly, and independently of any of the changes now adduced. It is thus impaired either congenitally or hereditarily, or by the injurious agents in operation during early life; and the consequences are a preternatural softness and flabbiness, and impaired vital cohesion, of all the structures, not excepting even the bones, which, as shown in rickets and scrofula, are not only slowly and imperfectly developed, but more or less softened, especially in their spongy parts. This *chronic form of general softening* may exist in the fœtus, without being hereditary; it may be hereditary, and yet not appear until some indefinite period after birth, as when it proceeds from scrofulous parents. It may be acquired from the nature or the supply of nourishment, or from the want of pure air, &c.; the scrofulous, or ricketty, or tubercular habit of body, being thereby produced in young subjects, and the scorbutic at more advanced ages. *Scurvy* furnishes one of the most remarkable illustrations of chronic general softening, or general impairment of vital cohesion, advancing in a slow and progressive manner, commonly in adults, *rickets* equally illustrating it in children. The general cachexia resulting from the *syphilitic poison*, or from *mercury* acting in poisonous doses or modes, or from the use of the *ergot of rye*, or from other poisonous substances, is chiefly characterised by softening, implicating, more or less, the whole of the structures, although manifested especially in certain tissues, particularly the cutaneous and cellular, the osseous and periosteal, the mucous,

&c., and, in certain of these, passing extensively into *ulceration*, of which softening is a general antecedent.

12. *E. Softening often depends upon the association, in various degrees, of the foregoing morbid states*, especially those causing partial or limited softening, and, even when thus associated, in its slighter grades it may be transitory, as when it occurs from œdema, or saturation of the tissues of a part with serum. Such saturation may proceed from local weakness of the tissue, or of the capillaries supplying it, or from more general debility, or from local changes, as obstruction in the returning circulation of the part, or obstruction of the absorbents, causing this lesion. The serous infiltration may be soon removed, or it may persist, or it may increase, and the attendant or consequent softening may also increase, and even go on to disorganisation; certain intermediate changes, however, sometimes appearing, especially asthenic inflammation. In these cases, the infiltration of serum, by its macerating property, weakens the vital cohesion of the tissue, or, by the possession of an irritating quality, induces a diffusive or asthenic inflammatory action, frequently passing into gangrene. The mere separation of the intimate structure of cellular or adipose parts, by the infiltration into it of an inorganised and inorganisable fluid, if continued long, tends to loosen the vital cohesion of the part; and when this fluid contains, as often occurs, excrementitious or injurious materials, the result is both increased and hastened, especially as it often also associates with it other changes, seated in the vessels supplying the part, tending most rapidly to gangrenous softening.

13. Œdema, or serous infiltration of the substance of the brain, whether the antecedent or the concomitant of softening of the cerebral structure (for it may be either the one or the other), generally induces and accelerates the softening process in this structure more remarkably than in any other organ; complete disorganisation, or decomposition, being thereby often rapidly induced.* Few parts, either by their physical condition, or by the nature of their organisation, are more frequently subject to serous saturation than the brain; and although the serous exudation is most frequently excessive between the membranes and in the ventricles; more or less fluid being always in these situations, — still the excessive accumulation of it in the ventricles will often affect the vital cohesion of the surrounding structure, so as to predispose to, or occasion softening in this situation or in the vicinity, especially in the scrofulous diathesis and in ricketty habits, in which the vital cohesion of the tissues is generally weak.

14. Congestions of blood in parts, asthenic and erysipelatous inflammations, the accumulation of excrementitial and irritating materials in the circulation, and the operation of animal and contaminating poisons, all in their several grades occasion more or less softening, which is most remarkably manifested in those tissues, the organisation of which is most loose or yielding, as cellular or mucous structures and parenchymatous organs. In these, especially, the softening is followed by the exudation of a fluid, which is neither pus nor concrescible lymph, even when the softening is most inflammatory, but which, in the scrofulous diathesis, is either tubercular, or curdy, or sanious, or an association of these; and in persons who are constitutionally exhausted, or whose blood is self-contaminated or otherwise poisoned, the morbid fluid, serous or sanious, infiltrates the adjoining tissues, softens them with various degrees of rapidity, and ultimately disorganises or decomposes them. These consecutive states of softening, whether manifested in external or internal parts, in cellular and adipose tissues, or in mucous or parenchymatous organs, are presented to our observation in the course of adynamic or malignant fevers, and after the absorption of puriform and sanious matters into the circulation, and in the several forms of erysipelas; and whether puriform matter be formed in the softened part, or a sanious fluid, or a foul, contaminating serum, infiltrating adjoining parts, they always tend to further disorganisation, or decomposition or gangrene supervenes, unless vital power and resistance be reinforced, and the contaminating state of the circulation be counteracted or remedied by suitable treatment.

15. II. THE THERAPEUTICAL INDICATIONS applicable to softening of structures, should be based upon the pathological states from which it appears to proceed, or with which it is associated. But the result of treatment will entirely depend on the acumen of the physician in detecting this condition of structure and the changes in which it originates, and in attributing to each its due influence, and in adapting his means of cure to their several grades and relations. When treating, under their proper heads, of the several states of softening, as manifested in different structures, I then pointed out the measures most appropriate for each; and, reviewing this lesion as one of the most advanced, and as one of the most dangerous, I then more especially considered the treatment most conducive to the removal of the changes from which it proceeds. Whether arising from inflammations, especially the asthenic,—or from congestions, hypostatic or others, — or from obstruction of vessels, arterial, venous, or lymphatic, — or from morbid matters conveyed into the circulation, and thereby affecting predisposed or previously disordered parts, — or from the diminution of certain elements necessary to vital density or cohesion, as phosphorus, or sulphur and their combinations, — or from morbid poisons changing the states of organic nervous power, and of the circulating fluids, more or less, generally, — or lastly from the nature of the food and from states of nutrition, — the treatment of softening of structure has received due consideration, as respects, not only this particular lesion, but also the changes from which it proceeds. In the several articles on ABSCESS (§§ 62.); ABSORPTION (§§ 15. *et seq.*); ARTERIES (§§ 40. *et seq.*); ARTS AND EMPLOYMENTS (§§ 23. *et seq.*); BRAIN, *softening of the* (§§ 214. *et seq.*); CACHEXY (§§ 4. *et seq.*); CELLULAR TISSUE (§§ 9. *et seq.*); CHOLERIC FEVER OF INFANTS (§§ 11 *et seq.*); CONGESTION OF BLOOD (§§ 12, 13.); DEBILITY (§§ 25. *et seq.*); DIGESTIVE CANAL, *softening of* (§§ 34. *et*

---

* It is not improbable, that softening of the nervous centres is favoured, if not caused, by a deficiency of sulphur or of phosphorus, or of both, and of their combinations, in the cerebral structure, these substances being always present, but in varying quantity in this structure, in its normal states.

seq.); Dysentery, Asthenic (§§ 88. *et seq.*); Erysipelas (§§ 64. *et seq.*); Fever (§§ 559. *et seq.*); Gangrene (§§ 57. *et seq.*); Hæmorrhage (§§ 40. *et seq.*); Heart, *softening of* (§§ 216. *et seq.*); Inflammation, Asthenic (§§ 236. *et seq.*); Intestines, *softening of*, (§§ 131. *et seq.*); Œdema, Pestilences, especially the Hæmogastric and Plague (*in numerous places*); and Scrofula.

16. In the treatment of softening of individual structures, as well as of the general softening of the tissues consequent upon malignant fevers, and morbid states of the circulating fluids, attention should be chiefly directed to those pathological states of which softening is the consequence; and these ought to be either removed or counteracted by means suited to these states, the most important of which have been indicated above (§§ 6. *et seq.*), or more fully mentioned in the articles just referred to. But it should always be remembered, that the removal of the causes; a supply of deficient elements, in medicines, aliments, and mineral waters; a suitable diet and regimen; a pure, dry, and bracing atmosphere, with free ventilation; a healthy discharge of the digestive functions, and the use of pure, or appropriate mineral springs, are the chief means of cure.

Classificat. — II. Class. — II. Order (*See Preface*).

Definit. — *Involuntary or abnormal actions of muscular parts: or, in other words, contractions of muscular structures, different in continuance, or in severity, or in recurrence from healthy action; constituting a generic pathological condition; and although most commonly a sympathetic, yet an important morbid state.*

1. I. Varieties of Spasm.—The ancients comprised under the term, spasm, all convulsive affections or movements, but the sense in which the word is now and more strictly applied, is the contraction or tension of a muscular structure, independently of volition, and often disposing to or followed by convulsion. Spasm, or cramp, frequently exists without convulsion, it may affect either voluntary or involuntary muscles; and, in either of these situations presents varying characters; and it may be attended by consciousness, or by an abolition of sensation, or even by various derangements of sensibility and mental manifestation. The supporters and followers of the nervous system of pathology, especially Stahl, Hoffmann, Juncker, Sauvages, Cullen, and others, attached great importance to this morbid condition, and sometimes inferred its existence, especially in internal and involuntary structures, where there was no evidence of its presence. Although the partial revival of the humoral pathology, to which the early articles of this work have in no small measure contributed, especially those on the Blood, on Disease, on Absorption, Excretion, Infection, &c., has, in some degree, diminished the importance which had been attached to spasm, as an influential pathological state, still it performs a part of considerable interest in the general doctrine of disease.

2. Sauvages arranged under spasm, all involuntary muscular contractions, and divided them into *tonic* and *clonic.* Under the former appellation he comprised those contractions which were, more or less, permanent or continued; under the latter he ranged those which alternated with relaxation; and both forms of spasm he divided into *partial* and *general.* *Partial tonic spasm*, according to him, embraced strabismus, trismus, torticolis, priapism, and cramp attacking any of the voluntary muscles. *General tonic spasm* consisted only of tetanus and catalepsy. *Partial chronic spasms* were carphologia, pandiculation, tremor, palpitation, &c.; and *General clonic spasms* were, eclampsia, epilepsia, hysteria, chorea, &c. Cullen adopted the view of Sauvages, in constituting spasmodic affections a distinct order of nervous diseases. Pinel, however, did not consider that the spasmodic state should be made the basis on which an order of disease might be founded.

3. It is very doubtful, whether or no, catalepsy should be viewed as a species of general tonic spasm, or even as a spasmodic affection at all. I have seen several cases of true catalepsy, and in these there was no increased action of muscles apparent. In cataleptic ecstacy, however, many of the voluntary muscles are, more or less, contracted; and when catalepsy occurs in connection with hysterical attacks, muscular contractions often precede the cataleptic state. In most of the convulsive affections arranged under eclampsia, epilepsy, and hysteria, the seizure is generally tonic at its commencement, and clonic towards its termination; so that it is very difficult to distinguish between those convulsive or spasmodic affections which are tonic, or which are clonic, these terms being altogether conventional, and the morbid states which they are intended to represent, passing gradually and insensibly from the one into the other.

4. MM. Pinel & Bricheteau divided spasmodic affections into those which are unattended, and which are attended by lesion of the faculties of intelligence. Dr. Mason Good arranged these latter, under the genus, "*Comatose Spasm*," assigning convulsions, hysterics, and epilepsy, to it, as species. But hysterical spasm is often unattended

by any comatose affection, or loss of sensibility; and here, as well as in other morbid conditions, the difficulty of classification becomes apparent. Dr. GOOD divided his order of spasmodic affections, or nervous disorders affecting the muscles, into three genera, consisting of "Constrictive spasm," of "Clonic spasm," and of "Synclonic spasm." The *first* of these comprised priapism, wry neck, distortion of the spine, muscular stiff-joint, cramp, locked-jaw, tetanus, rabies, and suppressed pulse; the *second*, hiccough, sneezing, palpitation, nictitation, subsultus, pandriculation; the *third*, tremor, chorea, shaking palsy, raphania and barbiers.

5. Dr. GOOD defined his genus "*Entasia*," or constrictive spasm, to be "irregular muscular action producing contraction, rigidity, or both." The genus *clonus*, or clonic spasm, he described as "forcible agitation of one or more muscles in sudden and irregular snatches," or, in other words, agitative or tremulous motions of the muscles. The genus *synclonus*, or synclonic spasm, he stated to be "tremulous, simultaneous, and chronic agitation of various muscles, especially when excited by the will," or a "multiplied conjunctive or compound agitation, or tremulous motion." The reader, upon consideration of the above definitions, will be at a loss to perceive the generic differences between the genera, clonus and synclonus, and he may not be satisfied that tremor and shaking palsy should be ranked as species of spasm.

6. Spasmodic action may occur in either voluntary or involuntary muscular structures. In the former it may be limited to one or more muscles, or extended to several, or even more or less generally; it may also, when so situated, be either simple, or associated with unconsciousness. In the latter class of structures, it is always partial or limited, and is generally complicated with irritation, or congestion, or inflammatory action, in adjoining or related parts. Spasm, moreover, is most frequently and strictly a *symptomatic* affection, and is rarely a *primary* or *idiopathic* disorder, unless when it occurs in the form of cramp, or from over-exertion of the muscles affected, or from bringing muscles that have been long disused into action.

7. Spasm may be arranged into, 1st., that affecting involuntary muscular structures, or those parts which are supplied only or chiefly by ganglial nerves; 2d., that attacking muscles which are influenced by voluntary nerves; 3d., spasm implicating both involuntary and voluntary structures; and 4th, spasm associated with want of consciousness. When spasm is seated in either involuntary or voluntary parts, it may be of varying duration; it may be continued for a time and then permanently relaxed; it may be thus continued and afterwards recurrent or convulsive; or it may be recurrent or agitative from the commencement, thus presenting either of, or all, the forms classed by Dr. GOOD as tonic, clonic, and synclonic, and being either partial, or limited, or more or less general. The limited states of spasm may be of considerable duration, and may even pass into a state of permanent contraction, although this may be a rare occurrence. Several of the unnatural positions of organs or parts, as those of the eye, extremities, &c., have been attributed to spasm of particular muscles; and probably the mal-position may have originated in this state, the contraction becoming permanent, whilst the spasm no longer existed; but it may have equally originated in a paralysed condition of antagonist muscles. In these cases care should be taken to distinguish between tonic spasm, permanent contraction of muscles or parts, and the deficiency of antagonist action.

8. i. *Spasm of involuntary structures* is an element of several diseases. It is most common in the digestive canal, in various parts of which it may exist in succession, generally in a recurrent, although sometimes in a more continued form. It may be limited to this canal, or be extended to adjoining parts, or even to voluntary organs. It may, when affecting the alimentary canal, be merely an exaltation of the peristaltic motion, as in diarrhœa or dysentery; or it may be more severe and attended by inverted action, as in vomiting, spasms of the pharynx or of the œsophagus. In these cases the spasmodic state is favoured either by extreme debility and sensibility of the seat of the disorder, or by inflammatory irritation, and is directly occasioned by any irritating substance. In any circumstance, the spasmodic action will be produced by irritations sufficiently great to excite it; and when the vital power of the parts is low, and the susceptibility great, even the accumulation of the natural secretions within these parts, or a vitiated state of the secretions, is sufficient to cause spasm, as evinced by certain states of diarrhœa, by vomitings, by colic, bilious cholera, &c. When any irritating body is brought in contact with the mucous surface of the digestive canal, whether that be gaseous, fluid, or consistent, spasm will generally affect the parts thereby irritated, or their more immediate vicinity. The same effect follows inflammatory action and ulceration, which are often followed by spasmodic action, as demonstrated in various parts of this canal, in the pharynx, the œsophagus, the stomach, the duodenum, the small and large intestines. Similar causes produce similar effects in the urinary passages, and even in the respiratory passages. In these latter the spasmodic action is often the most remarkable, and is generally followed by very manifest effects.

9. Various involuntary canals or parts have been supposed to be seats of spasm in certain disorders without sufficient reason. Thus the gall-ducts have been accused of spasm in some states of jaundice, and the capillary vessels in the cold stage of fevers. That irritating or morbid bile, or irritants at the mouth of the ducts in the duodenum, may cause spasm of these ducts, is very probable, but there is no palpable demonstration of this effect. That there is an apparent constriction of the capillaries, especially of those on the surface of the body, is very manifest in the cold stage of fevers and in states of vital depression; but it does not follow that the constriction is the consequence of spasm. It is merely the result of the contraction of these vessels upon a deficient amount, or the entire absence, of their contents, which are no longer propelled with sufficient power to fill or distend them, during these states of the frame.

10. Spasm of the parietes of the cardiac cavities has also been inferred to be present in cases of nervous palpitation; and when death has taken place suddenly, without any manifest organic lesion. That nervous palpitation is truly spasmodic, even when most exalted, is extremely doubt-

ful. There is certainly remarkably increased action and impulse with all the symptoms described when treating this affection of the heart (*see art.* Heart, §§ 43. *et seq.*); but morbidly increased action is not quite identical with spasm, although often nearly approaching it. With increase of action, prolongation or irregularity of the contraction is generally present in the spasmodic state. If we admit the occurrence of spasmodic or spastic contraction of the parietes of the heart of a much longer duration than that which takes place normally, death must necessarily follow; but I much doubt the existence of this lesion, especially in such grade or continuance as to occasion death. It certainly has not been satisfactorily demonstrated, although admitted by some writers.

11. ii. *Spasm of voluntary muscles or parts* is of frequent occurrence, either in the form of cramps of particular muscles, or in that of convulsive action of several or many. Cramps in the extremities may follow over-action of the muscles attacked, or be symptomatic of disorder of the digestive canal, or of latent or inflammatory changes in the brain or spinal chord, or their membranes, or of the irritation produced by the circulation of effete or injurious materials in the blood, as in cholera, gout, &c. They may even follow a certain amount of pressure upon, or irritation of the nerves, supplying voluntary parts, either at the origins, or in the course of these nerves, with or without any other manifest disorder. Cramps or spasm, of the lower extremities especially, often precedes, recurring at intervals, for some time an attack of paralysis or apoplexy, particularly hemiplegia; and they often recur, in slighter grades, during the restoration of the lost power. Spasmodic actions of voluntary parts may result from irritations in their vicinity, or in situations more or less remote, from irritations immediately affecting the nerves supplying these parts, or mediately and indirectly conveyed to them from a distance, as in trismus, tetanus, &c.; and the spasmodic action may be tonic or continued, or irregular or convulsive, or clonic or agitative, or recurring at intervals and occasioning snatches or startings, and various abnormal motions; or it may pass in succession through all those, as in irregular convulsions, in some forms of hysteria, and even in some cases of epilepsy. The spasmodic state, however, is subject to so many variations and anomalies, that it is quite impossible to describe them correctly in all their details at this place. Those diseases, in which spasm, in any of its forms, constitutes a principal element, are fully described, and with especial reference to this morbid condition, under their special denominations; it is requisite, however, to notice certain associations of this condition.

12. iii. *Spasm may affect both involuntary and voluntary parts.* It may extend from one order of parts to the other — most frequently from the former to the latter, if the succession of morbid phenomena be closely analysed, although voluntary parts manifest this disorder most evidently. Spasm, even when affecting most severely the voluntary muscles, may proceed from very remote sources of irritation, as I have shown in several places in this work before the subject was duly considered by any one else. Commencing with those sources which are the nearest to the parts which are morbidly contracted, and concluding with those which are the most remote, we find that muscular structures may experience unnatural action or spasm in some one of its varying forms, — 1st., from irritation in or near the seat of morbid action, as shown more especially in muscular canals — in the digestive, respiratory, and urinary passages; 2d., from irritants affecting the nerves supplying the affected muscles, as evinced in both involuntary and voluntary parts; 3d., from irritation or lesion of the spinal marrow at or near the origins of the nerves supplying these muscles; 4th., from lesion (not necessarily structural) of parts of the brain, or of its membranes, having relations with the nerves going to the convulsed or spastic muscles; 5th., from irritation of any portion of the digestive viscera and canal, or of the generative and urinary organs transmitted by ganglial nerves to the roots of the spinal nerves, or to the spinal cord, and reflected thence by voluntary nerves to the external muscles and members; 6th., from irritation of any of the senses — of hearing, sight, smell, taste, or touch — transmitted to those parts of the nervous centres with which they are respectively in connection, and thence reflected upon parts intimately related to them; thereby producing startings, tremors, sneezing, cough, retchings, or convulsive movements, as either of these senses are irritated or abnormally excited. These several sources of spasmodic action have been sufficiently illustrated in the articles Chorea, Convulsion, Epilepsy, Hysteria, Sympathy, Tetanus, &c.

13. II. Causes of Spasm. — i. *The predisposing causes* are the same as those fully described when treating of the individual species of spasm, these causes being generally common to all the species, the exciting causes, and the several intrinsic circumstances or peculiarities of the patient determining the form of the attack. Hereditary vice or disposition, congenital conformation, a weak development of frame, the female sex, a warm and humid climate, the ages of infancy, childhood, and puberty, the critical epochs of females, premature sexual indulgence and masturbation, luxurious indulgences and voluptuous modes of living, prolonged indulgence in bed or in sleep, inordinate devotion to music and poetical studies, excitement of the imagination, want of repose, mental anxiety, sleeplessness, exhausting discharges, the sudden suppression of accustomed evacuations, or of external pains; the gouty and calculous diathesis; excited and ungratified, or insufficiently gratified, sexual passions; suppressed emotions; the period of utero-gestation, the puerperal states, abortions, exhausting lactation, inanition; extreme states of vascular plethora, or of anæmia, &c., severally predispose, and often directly produce, some one or other of the usual forms of spasmodic disorder, or such states of spasm as may be considered as anomalous, or different from those commonly described by nosological writers.

14. ii. *The exciting causes of spasm*, whether specific or anomalous, are chiefly influences affecting the mind, the senses, the nervous centres, the alimentary canal and digestive viscera, the sexual and urinary organs, &c.; more especially the violent emotions of mind, whether manifested or suppressed; severe disappointments and losses; strong or strange impressions of the senses, startling noises, disgusting or horrible sights, objects of terror or surprise; violent excitement and the influ-

ence of the imagination: titillation or irritation of the more sensitive parts of the surface, prolonged or violent pain; disordered dentition and dental affections; derangements of the digestive canal, particularly the presence of worms, or of acidity, or of flatus, or of morbid secretions and excretions, or of fæcal accumulations; the passage of biliary calculi, or of disordered bile; irritation or excitement, or functional or structural lesions of the sexual or urinary organs or passages, calculi in the kidneys or bladder; inordinate or prolonged muscular action; various organic lesions or external injuries, implicating either the parts affected, the nerves supplying them, or related portions of the nervous centres or their membranes; sudden or extreme changes of temperature, or electrical conditions of the atmosphere; sudden suppression of discharges, eruptions, or external pain; the drying up of chronic ulcers; the nature of the ingesta, especially acid or unripe fruit, poisonous articles mistaken for food; the poison of lead, and numerous other injurious substances mentioned under the head of POISONS.

15. iii. *The immediate or efficient cause of spasm* — the pathological condition constituting this affection — has been a topic of contention among pathologists. It was generally ascribed to irritation of the nerves supplying the affected muscles, either at their origins, in their course, or at their terminations; or to a sympathetic affection of these nerves propagated from distant but related parts to those thus attacked; or to an irregular distribution through the nerves of the nervous influence or power, and determination of this influence to the affected parts. Towards the close of the last century, RITTER, SPRENGEL, and others, viewed spasm as a result of an alteration of the polarization of the terminations of the nerves in relation to the muscular fibres; and this doctrine, after having been neglected for half a century, has been revived at the present day, and supported by the connection established between magnetism and electricity. This latter theory may admit of a certain degree of practical proof, by having recourse to electricity or galvanism, or of electro-magnetism for the removal of spasm, an energetic recourse to either of these, overcoming, as it does in slighter cases, as shown by my own observation, the morbid condition of the muscles. Nevertheless, the same agencies may be viewed as equally successful in the removal of spasms, on the assumption of their dependence upon the irritation of the nerves in any way related to the affected parts. The *juvantia* cannot always prove the nature of the affection. I have seen, as far back as 1820, the most severe cases of tonic and of clonic spasm produced by the internal strangulation of a minute portion of the small intestines, and by the irritation of worms in the bowels, the violent affection of the voluntary muscles having arisen from those causes and ceased with them, the irritation having been propagated by ganglial nerves to the roots of the spinal nerves, and thence reflected upon the muscles in whch these latter nerves terminated; the history of these and numerous other cases favouring rather the old doctrine of irritation of nervous distributions than the less old and recently-revived theory of altered polarization of the nervous fibres, with relation to the muscular tissue, in producing spasmodic actions.

16. III. DIAGNOSIS OF SPASM.—The existence or non-existence of spasm is in many cases remarkably evident; but, in many others, even as respects some disorders which have been viewed as spasmodic, the evidence is by means satisfactory. As to the insufficiency of this evidence in regard of some disorders, I have already hinted. We have no proof of spasm in any quarter in cases of *catalepsy* of a true pathological form; at least, I could detect none upon a close examination of several cases. The several forms of true *tremor*, as arising either from mental emotion, or from mineral or other poisons, or from functional or structural changes, evince no true indication of spasm. The disordered motion is merely the result of an imperfect determination or transmission of nervous power to the tremulous parts, owing to an insufficient or an interrupted supply of this power from the voluntary or involuntary nervous sources, as either voluntary or involuntary parts are affected.

17. Various *paralysed parts* may present states which may be mistaken for spasmodic affections; and the paralysed state may rapidly pass into the spasmodic, and this latter into the former, which is much the most common. The existence, the morbid relations and the transitions of both these morbid conditions thus become extremely important. *Hysteria*, the *convulsions*, and other spasmodic and anomalous affections of infants and children; diseases of the brain, or of its membranes, in the same class of subjects; diseases or injuries of the spinal marrow, &c.; epilepsy, apoplexy, paralysis, &c., either frequently or occasionally, present more or less of spasmodic action, often passing suddenly or rapidly into one of entire loss of power. The irritation, softening, effusion, compression, or other original morbid change affecting the nervous centres, whilst slight, or in a lesser degree, may occasion only cramps (spasmodic motions), but, when increased relatively to the state of nervous power, may cause the loss of all motion. We thus often observe, that several maladies commence with more or less of spasm, or cramps in the extremities, especially the lower, and soon pass into the paralysed state; apoplexy, epilepsy, paralysis, and various other specific and anomalous affections of the nervous system, manifest in many instances this succession of lesion and of resulting phenomena.

18. Dr. M. HALL is of opinion, that the spasmodic affections ushering in many cases of these maladies commence, or are seated, in the superficial muscles of the neck; and that the spasm of these muscles, by compressing the larger veins, occasion congestion of the brain, and the several consequences of congestion when the spasm is not soon relaxed. He believes that "certain causes and principles, emotions and irritations, act directly or diastaltically upon the muscles of the neck," inducing what he designates "*Trachelismus*": — "If this spasm can be dissolved, all its effects cease more or less perfectly." That the muscles of the neck are affected with spasm in many cases of hysteria, especially in the more severe or paroxysmal, cannot be doubted; and that those seizures which originate in violent mental emotions are often thus characterised, or even thus originate, may be conceded; but the spasm of these muscles is not so general, nor always so early in the procession of morbid phenomena, as Dr. M. HALL supposes. When it does exist, and is either severe or protracted, the consequences which fol-

low are generally serious; and it then constitutes an important portion of the courses of morbid actions and changes, each successive portion being the cause of that which follows it, as it is itself the consequence of that portion which precedes it.

19. Spasm of involuntary muscles must necessarily be imputed to irritation of the ganglial nerves supplying these muscles, or to some alteration in the relations subsisting between the nervous and muscular fibres of the affected part. But when spasm attacks voluntary muscles, the irritation has been generally supposed to be seated in, or to implicate, the voluntary nerves. It is, however, very doubtful whether the spasm of these muscles is so generally caused by irritation of voluntary nerves as is commonly believed. It is very probably so caused in many cases, as shown by injuries of the spinal chord, and by inflammation of this part of the nervous system or of its membranes; but there are various diseases, in which spasm performs a chief or a subordinate part, where irritation of any part of the voluntary nervous system is by no means demonstrable, either the muscular fibres or the ganglial nerves supplying them being much more probably the primary seat of such disorder. In trismus and tetanus, in which the voluntary muscles are so severely contracted, there is no proof that the voluntary nerves are primarily implicated; for volition produces no effect on the spasm, and whatever lesion these nerves present, in some cases merely, may be consecutive much more probably than primary. In the most severe cases of spasmodic cholera, in violent cases of colic or ileres, and in others where a very limited injury is sustained by a portion of intestine, as in partial strangulation, I have seen the spasm of the voluntary muscles as general as in tetanus, and continue in this state for long periods, and yet the cerebro-spinal nervous system must be inferred to have been free from all irritation but what was propagated to the spinal nerves from the ganglial nerves supplying the digestive canal.

20. IV. The Prognosis of Spasm may be most favourable, or the most fatal, according to the seat of spasm, and the circumstances in which it occurs. A spasmodic affection may terminate the life of an infant in a few seconds, especially when it is caused by disease about the base of the brain, or near the medulla oblongata, or thin membranes; or it may cease in a very few minutes, where it is produced by acidity or by any other source of irritation in the alimentary canal. Clonic spasm of the diaphragm may arise, especially in young persons, from the deglutition of a hard or imperfectly masticated substance, or from acidity, flatulence, &c., or it may be the indication of a fatal issue in many acute and even chronic diseases. It may proceed from inflammatory action or irritation of one or more of the digestive organs, or from the sinking of vital power preceding dissolution.

21. Spasm affecting either involuntary or voluntary parts is not attended by danger when it occurs in hysterical or nervous females, or when it cannot be traced to disease or injury of the brain, spinal marrow or their membranes, or to antecedent or existing visceral disease, pectoral or abdominal. When however it has been preceded or is attended by inflammatory action, or by hemorrhage, or even by evidence of congestion of any important organ, or by effusion into any cavity, especially if hæmorrhage has been excessive or effusion great, spasms of any part, and more particularly if they affect the diaphragm, or even the pharynx, œsophagus, or stomach, are a most unfavourable, and generally a fatal, symptom.

22. Spasms of either voluntary or involuntary muscles are always indications of great danger when they appear in the course of malignant or other fevers, and especially in an advanced stage of those fevers, or when they are present in pestilential distempers, or at the commencement of acute inflammation of abdominal organs or at an advanced stage of chronic visceral or structural disease; the amount and imminence of danger depending upon the violence or malignity of the disease, upon the contamination of the blood, upon the stage of the malady at which spasms occur, and upon their seats and extension. Spasms affecting the muscles of the superior extremities are always much more dangerous than those of the lower extremities, and, when they extend from the former to the latter, the danger is extreme.

23. Spasms of voluntary muscles attending gout or rheumatism are readily removed when they are caused by acidity and flatulence, or accumulation of morbid secretions and excretions in the intestinal canal or in the biliary organs; but when in these diseases spasm appears independently of the disorders just mentioned, or when structural change is detected in the heart, or when the state of the urine indicates disease in the urinary organs or passages, more or less danger should be apprehended; and, although present risk may be averted, a future attack, with its contingent danger, may supervene sooner or later.

24. Spasmodic attacks consequent upon protracted lactation, upon menorrhagia, or profuse leucorrhœa, or upon other exhausting discharges, or upon manustupration or venereal excesses, or upon inanition or anæmia, are frequently temporarily removed by treatment; but they return, or assume a more serious aspect, if the morbid condition in which they originate be not removed by appropriate means, or they may pass from the hysterical character, in which they generally first present themselves, into the epileptic or into mania or confirmed insanity.

25. Spasms occasioned by the extent or seat of injuries generally excite great anxiety, and are most frequently attended by danger. But the amount of danger, or even the absence of it, depends chiefly upon the nature and seat of injury, and the amount of vital shock (*see art.* Shock), attending it. When the cranium or spinal column is the seat of injury, when there is a penetrating wound or compound fracture, or when vital sinking indicates the violence of the shock sustained by the frame, the presence of spasm not merely complicates the injury, but also indicates its severity, and the imminent danger attending it.

26. V. Treatment. — It is obvious that the treatment of spasm should in great measure depend upon the seat and nature of the disease, of which the spasmodic symptoms form either a subordinate or a most prominent part. When the spasm is more than a symptom, depending upon some special malady; when it constitutes an early, predominant or principal morbid condition, either with or without loss of consciousness, it presents,

according to its antecedent or associated and peculiar phenomena, certain special forms, which are described under the several heads of *chorea*, *convulsions*, *epilepsy*, *hysteria*, &c., and for each of which, in its several varieties, the treatment is fully described. It therefore remains only to state those general principles or indications which experience indicates or contra-indicates, under certain circumstances and morbid conditions with which spasm is generally allied.

27. It would appear from what has been stated above, that one or other of the different forms of spasm is contingent upon, or is produced by, one or other of the following pathological states, — 1st, congestion; 2ndly, inflammation; 3rdly, irritation caused by acid, acrid, or otherwise disordered secretions and excretions; 4thly, a contaminated state of the circulating fluids; 5thly, some structural lesion or injury affecting adjoining or remote nerves or the origins of nerves; 6thly, extreme exhaustion of organic, nervous, or vital power; 7thly, the excessive action of muscles, and the contraction of muscles independently of a co-ordinate or sufficient determination of volition to them; 8thly, punctures or other injuries of tendons, nerves, or fibrous membranes; 9thly, the irritation of the sexual or urinary organs; and 10thly, two or more of these states conjoined. It will be seen, from a consideration of these antecedents, that spasm is most commonly a symptom of certain disordered or morbid conditions, to which attention should chiefly be directed in its treatment, and that it is only when produced as just indicated in the seventh and eighth of the above series of causes or circumstances, that spasm can be considered as a primary or idiopathic disease. (See arts. Tetanus and Trismus.)

28. *A. Congestion*, in connexion with spasm, may be viewed both as an antecedent and associate of this latter condition. It may, moreover, be further associated, as with irritation or some structural lesion; and as long as these are in existence, so long may the spasm continue or recur, as various concurring causes may favour its return. The existence of congestion is often difficult to determine; for when the spasm implicates any part of the respiratory apparatus, or when it is so general as to give rise to convulsions, with or without loss of consciousness, the congestion which is then made manifest is more the result of the spasm than the cause of it. Congestion of the brain, or near its base, especially if consciousness be lost, and congestion of the lungs and cavities of the heart, are common effects of general spasm or convulsions, especially when any part of the respiratory passages is affected. Congestion may certainly exist in either organ antecedently to either spasm or convulsion, for it is frequently the cause of both; but the spasm may increase the congestion, and it may even be the cause of relaxing the spasm when the congestion becomes extreme. This latter effect takes place chiefly in extreme congestion of the brain, when consciousness is lost; the congestion, in connexion with the circulation of imperfectly oxydised blood in the brain, both relaxing the spasm and permitting the renewal of air in the lungs. The more moderate congestion in these cases first occasions spasm or convulsions; but when the congestion of unoxidised blood, increased by the convulsions, becomes extreme, then the spasms are relaxed and altogether resolved, and either natural respiration is resumed, or death takes place from the cessation of respiration, owing to the effect produced by the congestion at the origins of the respiratory nerves. In cases of spasm, thus arising or thus associated, the treatment must be directed by the following intentions: namely, 1st, to diminish or remove congestion by means which experience has shown to be most efficacious in obtaining this object; 2ndly, to prevent the recurrence of this condition and its contingent effects.

29. *a.* Spasm depending upon or connected with congestion of any vital or important organ has been too generally treated by large vascular depletions, both general and topical. In young, robust, and plethoric persons, and when the spasms have been consequent upon the stoppage of accustomed discharges, both the one and other mode of depletion may be employed, but with extreme circumspection, more especially during the attack. In most even of these cases, local depletions are the safest and most efficacious; for when the circumstances just mentioned as warranting the depletion are not manifestly present, or when the patient is of a nervous temperament, either the local depletion should be small, or it should be altogether dispensed with, and other means be chiefly confided in. When local depletions are indicated, cupping is the most beneficial; and when the loss of any blood is justly dreaded, then dry-cupping may be resorted to. The circumstances indicating depletions, as well as those contra-indicating them, require for their recognition great discrimination, guided by an enlightened experience, and are such, in their natures, complexities, and varied successions and associations, as to be estimated correctly only at the moment by the closely observing physician. When therefore there is any doubt as to the propriety of bloodletting, it will be preferable to resort to dry-cupping, and to emetics and purgatives, conjoined with stimulants and antispasmodics, — with these latter more especially when nervous energy is much reduced or originally weak.

30. *b. Of emetics*, especially when spasm is imminent, or when it attacks any part of the respiratory apparatus, the most energetic is the *tinctura Lobeliæ*, or *Tinct. Lobel. Ætherea*, given with vinum ipecacuanha to ensure its emetic operation, or with sulphas zinci. When vital or nervous power is much reduced, it may be given with spiritus ammoniæ aromaticus, or with camphor. When bloodletting is manifestly indicated, or when congestion of, or vascular determination to the brain is urgent, then depletions and derivatives, as mustard pediluvia, should precede the exhibition of an emetic; and the affusion of cold water on the head, or cold sponging, may also be practised, the emetic operation and the relaxation of spasm being often promoted by these means. When congestion of the liver is connected with spasm, local depletion or dry-cupping, or both, are often required, and then the preparations of colchicum may be given, at first in a large dose, either with or without an emetic conjoined, and afterwards relinquished for purgatives and antispasmodics. The operation of the first dose of colchicum should be carefully watched, particularly when large, and, if vital depression follow it, stimulating antispasmodics, as ammonia, camphor, valerian, &c., be exhibited. The spasms or

convulsions which sometimes occur on the invasion of exanthematous fevers, are often connected with congestion; and for these an emetic and a warm bath are often of service.

31. *c. Purgatives* are generally beneficial, more especially when the liver or brain is congested, and when the spasm is connected with acidity and flatulence of the digestive canal, or with accumulations of morbid secretions, excretions, and fæcal matters, as when spasms occur in colic or in the course of gout, rheumatism, hysteria, hypochondriasis, &c. In these, as well as in some cases of other diseases, not only are morbid excretions thus liable to accumulate, but the blood becomes more or less contaminated by effete materials, which the impaired functions of the emunctories fail of removing. In these circumstances, purgatives should be selected with the view not merely of evacuating the contents of the bowels, but also of promoting the functions of excreting organs. When cerebral congestion is connected with spasms, then active derivative purgatives ought to be exhibited by the mouth and in enemata, and with this view, as well as with the intention of removing spasms by one of the most powerful antispasmodics that can be prescribed, a full dose of spirit of turpentine should be given with castor oil, or with other purgatives, and administered in an enema. When the liver is congested or torpid, as may in many cases be ascertained by percussion, then calomel with camphor, and various other chologogue purgatives, will be most appropriate.

32. *B.* When the spasm is contingent upon *Inflammatory Action*, recourse to vascular depletions, general or local, is commonly required; and what has been stated above (§ 29.) respecting bloodletting is also here applicable to a great extent. It should always be recollected that inflammations accompanied with spasm or convulsion rarely admit of vascular depletions to the same amount as will be safely and advantageously borne in pure uncomplicated inflammation. Indeed the depletions may even increase the spasm without materially diminishing inflammation when injudiciously employed, or when confided in chiefly, and when the inflammation is of an asthenic character. In this latter state more especially, and in other circumstances of this morbid alliance, deobstruent purgatives, conjoined with stimulants and antispasmodics, are required; and even in cases where vascular depletions are most indicated, not merely such purgatives, but also stimulating antispasmodics, may be most beneficial, with other restoratives which the peculiarities of the case will suggest. In some instances an emetic, judiciously selected and combined, will also be of much service, after depletion has been resorted to, when clearly indicated. In the worst form of spasm, as in that contingent upon asthenic or cachectic inflammation, for which bloodletting is generally more injurious than beneficial, the early exhibition of an emetic, followed by purgatives, and by tonics conjoined with alkalies, antispasmodics, counter-irritants, &c., will be found more certainly useful than other means.

33. Spasms of the voluntary muscles, either limited or more or less extended, are often produced by inflammation at or near the origins of the nerves supplying the affected muscles, or by inflammatory action, or irritation of the membranes in the vicinity, or by disease of the adjacent bones, as shown when treating of lesions of the *brain*, *spinal chord*, and *membranes*, or of the *cranium* or *spinal column;* and for these, although general or topical bleeding may be requisite, according to the nature and features of the case, purgatives, alteratives, derivatives, counter-irritants, sedatives, and the other means fully set forth in these articles, are especially required.

34. *C.* The dependence of spasm on *acrid, morbid, or other irritants in the digestive canal*, is of frequent occurrence, both primarily and unconnected with any special malady, or so associated, as in gout, hysteria, &c. In all these circumstances, emetics, purgatives, anthelmintics, &c., as above recommended (§§ 30. *et seq.*), are indispensable. In the gouty and rheumatic diathesis, equal parts of magnesia and sulphur, taken on several occasions, and followed by a more active cathartic, will be found efficacious; and if there be reason to infer the presence of worms, the spirit of turpentine with castor oil, or anthelmintics, purgatives, &c., will be generally indicated; but they should be afterwards followed by chalybeates, tonics, and antispasmodics, as recommended in the article on Worms.

35. Irritation of the higher portions of the alimentary canal by the irruption of acrid bile into the duodenum often occasions spasms of the abdominal muscles, and calves of the legs, but these generally subside after the evacuation of the morbid matters; dilution of the acrid secretions by warm emollient fluids, narcotics subsequently, and mild purgatives afterwards, effecting a complete cure, generally in a short period. (See Cholera, &c.)

36. *D.* Spasm is not frequently occasioned *by contamination of the circulating fluids*, unless at a far advanced period of febrile and pestilential diseases, as in pestilential cholera, and when the functions of the kidneys are impaired, interrupted, or otherwise disordered. In these circumstances vital power requires support, whilst morbid matters are evacuated, and the actions of the depurating organs are excited by their appropriate stimuli. We should, moreover, endeavour to change or counteract the influence of those materials which thus accumulate in the blood,—to remove or neutralise them. They can be removed only by increasing the functions of the emunctories, and they may be neutralised by appropriate alkaline or mineral agents, and by antiseptic and antispasmodic medicines, as recommended when treating of the maladies in which spasms are most frequently observed.

37. *E. Structural lesions, injuries,&c.* of the bones, or membranes near the origins, or in the course of, the nerves supplying the extremities or voluntary muscles not infrequently occasion spasm of these muscles, and require the means already recommended (§§ 29. *et seq.*), modified according to the nature of the lesion or injury, and to the peculiarities of the case in other respects. In these states of disease the performance of the several excreting functions requires especial attention, and the evacuations a particular examination.

38. *F. Extreme exhaustion of vital or nervous power*, causing spasm or irregular or convulsive actions of voluntary muscles, or of involuntary parts, is often irremediable, especially when it appears at an advanced stage of pestilential or febrile mala-

dies, or after large losses of blood, and in the course of exhausting or contaminating diseases. In these circumstances powerful stimulants and antispasmodics—wine, opium, camphor, ammonia, oxide of bismuth, ammoniated copper, cajuput oil, phosphoric acid, the preparations of sumbul, arnica montana, the ethers, brandy, &c. — are necessary, and one or more of these may be conjoined with such preparations of iron, or of assafœtida, or of valerian, of zinc, of silver, of phosphorus, canabis Indica, or of musk, castor, &c., as the peculiarities of the case will suggest.

39. *G.* When spasm or cramp is caused *by excessive action of the affected muscles*, or by contractions of muscles without a due determination of volition, it generally soon ceases, and requires merely frictions and quiet. If it recur, friction with stimulant liniments, the application of warm embrocations near the origins of the nerves or portion of the spine enclosing these origins; frictions with chloroform or æther, or with turpentine and camphor, either over the affected muscles, or along the spine; and subsequently the cold douche or affusion, or sponging the spine night and morning with a tepid or cold solution of bay-salt, followed by gentle friction with the hair glove, &c., will generally prevent a recurrence of the spasm.

40. *H. Punctures or injuries of tendons, &c.*, are occasionally followed by trismus or tetanus, the most continued and dangerous form of spasm, and one which requires, more than almost any other disease, the most energetic stimulants, antispasmodics, and tonics; the powerful doses of sedative and narcotic substances generally resorted to for this affection tending rather to hasten than to avert dissolution. (See arts. TETANUS and TRISMUS.)

41. *I.* The *influence of the sexual organs* in producing spasm or convulsion is especially manifested by the female. But there are often other morbid conditions present besides either irritation, congestion, or inflammatory excitement, or vascular determination of these organs. Generally nervous power, especially organic nervous power, is exhausted or depressed, the secretions disordered, and the excretions insufficient or retained; consequently assimilation is impaired, and the blood poor. The affection of the sexual organs is readily induced by mental emotion or desire; and this affection reacts upon the brain and nervous system generally, is propagated by the ganglial system to both the abdominal and thoracic viscera, disordering the functions of the urinary organs, occasioning spasmodic actions of the alimentary canal, respiratory organs and passages, and often exciting spasms or convulsions, or both, by the extension of the irritation to the roots of the spinal nerves, and even to the spinal marrow, medulla oblongata, and brain.

42. The treatment hitherto recommended in these cases has consisted chiefly of stimulants and antispasmodics, and have been but insufficiently directed to the sexual organs and to the mind. The morbid or irritated state of these organs should be removed, and sexual desires suppressed. Instead of stimulants and heating antispasmodics, cooling medicines, as nitre, small doses of camphor, magnesia, alkalies, &c., should be given in bitter infusions, and the mind ought to be occupied agreeably and profitably. When spasmodic affections occur in females or males, especially if the countenance become pallid or sallow, then the most noxious vice of all vices should be suspected, namely self-pollution (see arts. DEBILITY and POLLUTION); and unless this be relinquished, and the mind be healthily and morally regulated, medical treatment will be of no avail. (See arts. CHOREA, COLIC, CONVULSIONS, EPILEPSY, and HYSTERIA.)

SPINAL COLUMN, DISEASES OF.—

SYNON. — *Vertebral column; Columna vertebralis; C. spinalis*, Auct. Var. *L'épine du dos, Rachis*, Fr. *Der Rückgrat*, Germ. *The Spine, Spinal Chord, and Membranes.*

1. I. PRELIMINARY REMARKS: — The spinal column has attracted to itself a due proportion of attention from medical writers only in comparatively recent times. The diseases of the several tissues, of which this column and its contents consists, were either altogether unknown, or overlooked, or if partially known, undeservedly disregarded, until J. P. FRANK, in 1791, published his celebrated treatise on the great importance of this part of the frame in disease. Previously to this period, disorders and lesions of the spinal column and chord received only partial and very imperfect notices from medical and surgical

writers. Some mention of the functions and diseases of these parts is to be found in the works of HIPPOCRATES, GALEN, ARETÆUS, and CELSUS; but the structure and functions displayed by them, more especially by the spinal chord, were very imperfectly investigated and understood, until BARTHOLIN and BLASIUS entered upon this undertaking. VIEUSSENS afterwards, HUBER subsequently, and MONRO, FROTSCHER, LUDWIG, GALL, and HOME, at later periods, cultivated still further this field of research. Injuries and diseases of the vertebral column were treated of by POTT, PALETTA, SOEMMERING, C. BELL, A. LOUIS and others; whilst the maladies implicating chiefly the spinal chord and its membranes were illustrated successively by VOGEL, PORTAL, BERGAMASCHI, BRERA, AUTENRIETH, MUSSY, SCHMALZ, RACCHETTI, CHOULANT, OLLIVIER, BRODIE, the author, and others; but it was not until the researches of C. BELL, MAGENDIE, M. HALL, VALENTIN, STILLING, VAN DEEN, BUDGE, &c., had thrown additional light upon the structure and functions of the chord, that the diseases of this organ and of its envelopes have been duly illustrated. Even at the present time, it is doubtful whether or not these diseases have received the full amount of investigation, which they have so long required. The reader will find, in the sequel, an account of the works furnished not only by writers now enumerated, but also by many others, who have contributed more or less to the present advanced state of our knowledge of diseases of the spinal column, and of the very important tissues which this admirable structure contains and protects.

2. *A.* It may not be disadvantageous to take *a brief survey of various topics connected with the pathology of the spinal column, and of the parts which it contains, especially in relation to certain agencies, and to other maladies, with which affections of these structures are often more or less intimately associated.*

3. *a.* During the several forms and stages of *fever*, periodic, continued, exanthematous and malignant, the functions of the spinal chord are more or less impaired or disturbed, as evinced by the pains in the back, loins, and limbs, and by incapability of assuming the erect posture, or even of moving. In the early stages of these maladies, these symptoms are manifestly due chiefly to congestion of the veins and venous sinuses of the vertebral canal, and to disordered circulation in the chord and its membranes; but, at more advanced stages, the morbid or contaminated state of the blood itself, and the failure of vital power generally, still further increase the deficiency of voluntary motive power, paralysing not only the limbs, but affecting more or less, through the medium of the branches of spinal nerves communicating with the ganglial and visceral nerves, the functions of the several internal organs, and especially of the urinary and genital.

4. *b. Rheumatism* and *gout*, the former especially, may attack, by metastasis or otherwise, the membranes of the spinal chord, and by the effusion of lymph between them greatly impair or entirely abolish either motion or sensation, or both, in parts supplied with nerves from or below the seat of effusion. A similar succession of disease may occur in the course of various acute eruptive maladies, although much more rarely.

5. *c. Scrofula, tubercles,* and *rickets* very frequently attack the spinal column, generally the bodies of the vertebræ, and produce the most serious effects not only upon these, but not infrequently also upon the membranes, the spinal chord itself and the roots of the spinal nerves, causing the several sympathetic disorders which will be described in the sequel. The affection of the spine may, in scrofulous subjects, be the only serious manifestation of the scrofulous taint, or it may be associated with, or consecutive upon, other outbreaks of this taint, in the form of tubercular infiltration or other structural lesions.

6. *d.* The affection of the spinal chord and membranes may be connected with *disorder of the sexual and urinary organs;* and, although the more severe affections of the former generally disturb or abolish the functions of the latter, serious or protracted disorders of the urinary and sexual organs not infrequently excite important lesions of the spinal chord. This latter procession of morbid phenomena admits of ready explanation. Exhausting seminal and other discharges from the genitals depress vital power generally, impair the requisite nutrition, and regeneration of the nervous influence of the chord; and thereby not merely weaken remarkably the functions of this organ, but affect its intimate organization, favouring softening or other structural change. Irritation also of the sexual organs, and of the urinary organs also, may be propagated by the communicating branches of nerves to the spinal chord, and, when thus extended and perpetuated by a continuance of the cause of irritation, serious lesions may be reasonably inferred to arise not only in the chord itself, but also in its several envelopes, and even in the bloodvessels lodged between these envelopes and the bodies of the vertebræ.

7. *e. Inflammatory affections of the nerves,* especially of those of the lower limbs, may extend even to the spinal chord or membranes, and produce in these similar changes to those which follow the metastasis of rheumatism or gout to these structures, or the suppression of eruptions, &c. This succession or extension of disease is rare, but a few instances have come under my observation, especially the extension of inflammatory sciatica to the sacrum and back, and the supervention of spasms, followed by loss of motion, &c.

8. *B. There are various symptoms, circumstances and complaints, several of them appearing obscure or anomalous, which ought to direct our attention to the spinal column, and lead to a very careful examination of its state and functions.* — *a.* The *voice* and *respiration* are often affected when the upper portion of the medulla or chord is in any way implicated in disease. I saw some years ago a gentleman who had been seized when a young man with hemiplegia, the speech, tongue, and muscles of the face having been affected. He was subsequently quite restored to health, and presented no indication of paralytic affection, and had for many years pursued his profession. But on the last occasion of his consulting me he complained of a form of hoarseness, or state of voice, which had been treated by more than one physician as a chronic laryngitis. I had arrived at first at the same conclusion; but an examination of the chest, throat, and neck, attention to his arti-

culation and voice, and the previous history of the case, convinced me, that the affection was more paralytic than inflammatory, and that he was in imminent danger of an attack of asphyxia, of apoplexy, or general paralysis, from lesions about the medulla or base of the brain. The treatment was directed accordingly; a seton was placed in the nape, but he died suddenly some time afterwards. The affection of the functions of respiration, and even of the actions of the diaphragm consequent upon disease of the medulla, or of its envelopes, was known to GALEN.

9. *b.* Since the days of GALEN (*De Locis affectis*, l. iii. c. 10.), the influence of the medulla oblongata and spinal chord upon respiration and the actions of the *heart* was overlooked until VERNAY, MORGAGNI, ELLER, ZINN, LE GALLOIS, PROCHASKA, BRODIE, and more recently W. PHILLIP, C. BELL, and M. HALL, directed especial attention to the subject. The last-named writers, however, imputed the action of the heart entirely or almost wholly to the nervous influence of the medulla, overlooked the more important influence of the organic or ganglial nerves abundantly supplied to the heart and respiratory organs, and directed their attention chiefly to, and over-estimated, the spinal nervous influence, which only reinforces and modifies the more important and greater — the more vital power—which the heart and lungs receive from the other source just named. There is no doubt that the mechanism of respiration — the respiratory muscles, are more especially influenced and actuated by the medulla and chord; and that whatever interrupts or intercepts the nervous influence from these sources, or from the more basilar and central parts of the brain, by causing asphyxia, soon arrests the actions of the heart. That the contractions of the heart may be rendered more energetic, more tumultuous or impulsive, either by mental emotion, or by irritation of the sources of nervous influence now named; or, on the other hand, that these contractions may become more slow, more weak, and even more irregular and intermittent, until death may supervene with more or less rapidity, owing to a defective or an interrupted, or an intercepted transmission of nervous influence from these sources, cannot be disputed. In cases, therefore, which present disordered action of the heart, of whatever kind, not only should this organ itself be carefully examined, but also the state of the spine, as far as that may be done, and the several manifestations of organic nervous influence, as displayed by the several digestive, assimilating, and excreting functions.

10. *c.* The abdominal muscles are subject not merely to *cramps* and *spasms* when the medulla spinalis or its membranes are diseased, but, even independently of cramps, the patient often complains of a remarkable increase of the sensibility of the cutaneous surface, of a sensation of girding or *constriction* around the abdomen or base of the thorax, subsequently of impaired sensation and motion, with great constipation of the bowels, retention of urine, and various other symptoms, according to the portion of the chord which is implicated. (See art. PARALYSIS.)

11. *d.* The limbs are often the subjects of *cramps*, or permanent *contractions*, often with an intervening sensation of *prickings*, numbness, and peculiar modifications of sensibility, especially near the points of the toes or fingers, with a sense of weight and numbness of the legs and feet, or of the whole limb. Occasionally these sensations are felt on one side only, or in both, or more severely in one than in the other; and, although they often precede an attack of gout, they frequently are precursors of organic lesions of the chord or its membranes, and thus usher in an attack of paraplegia, or inflammation of the chord and its membranes, or accompany inflammation of the intervertebral cartilages, or caries of the bodies of the vertebræ.

12. *e.* More or less *severe pain* or *neuralgia* may be complained of, in some remote part from the spine, or in one or more limbs, often in the extremities, but as frequently deep-seated in the middle of the thighs, or in the abdominal muscles, or between the ribs, the pain often admitting of being traced to the origin of the affected nerve in the spine. The effect of position upon the pains—of standing, or sitting, or lying down in the prone or in the supine position; and the periods of the day or night when they are most acute, ought to be carefully ascertained. In cases of inflammation of the chord, or of its membranes, or of the bodies of the vertebræ, the pain is much increased towards morning and after lying upon the back, and extend around the abdomen and down the limbs, with at first retention of urine, constipation, and subsequently loss of power of the sphincters. If, however, the inflammation be slight, and the patient has not retained the supine posture during the night, the pain may be diminished in the morning, owing to augmented capacity, by elongation, of the spinal canal.

13. *f.* The state of the *sexual functions* are often much disordered in diseases or injuries of the spine or of the chord. Whilst masturbation, or sexual intercourse, when excessive, may impair the nutrition of the chord, and induce disease both of it and its membranes, the latter occasions, particularly when the lesion is low in the chord, loss of sexual power, and incontinence of urine. Injuries or acute disease in the cervical portion of the chord are often attended by priapism.

14. *g.* The above and other phenomena, which will attract the attention of the observing physician, will always suggest to him the necessity of having recourse to a careful examination of the spine; and even when none of the above is present, the patient, however, presenting unusual debility, or impairment of activity or motion in the lower extremities, or great weakness or trembling of the knees, with a bent, staggering, or unsteady mode of progression, emaciation of the lower extremities, relaxation of the ligaments of the joints, &c., the experienced observer will infer impaired nutrition and function of the spinal chord, either from the exhaustion produced by masturbation or excessive sexual indulgence, or from congestion of the venous sinuses of the vertebral canal, or from incipient softening or other structural change in the chord, or in its membranes.

15. *h. An examination of the spinal chord* should be commenced with a careful inspection of it in various positions — whilst standing erect, whilst the trunk is bent to either side, and when the patient is prone. The effect of bending or turning quickly to either side should be observed; for, even in incipient caries of one or more bodies of the vertebræ, the patient sometimes experiences a

sensation, grating, or crepitation, on making any of those changes of position. The sensibility of the surface of the trunk and limbs, the temperature and state of the skin, and the degree of rapidity with which volition is conveyed to the extremities ought to be noted. The clavicles, the ribs, the sacrum, the crests of the ilia and hips, should also be noticed, in respect of their particular states, and of their relations to the spine; for by their aid, relative position, and direction, incipient states of curvature may be ascertained. The effects of pressure and of percussion over the spinous process of each vertebra, and over the outlets of the spinal nerves, should be carefully observed. It has been supposed that the pressure of a hot sponge directed over the vertebræ will detect subjacent lesion, and point to its exact seat when other modes of having recourse to pressure will fail. I have not observed much advantage from this mode of examination, but it need not be neglected; inasmuch as the more fussy and the more particular, and the more singular the mode and means of examination resorted to, even when the nature of the case is as clear as sunshine, the more they will attract the observers, both interested and disinterested, and accord with the prevailing ad captandum minuteness and professional manipulations of the day. If there be no occasion for a graceful display of the stethoscope—and when may not such be necessary, or made apparently requisite? And if there be no requirement for the introduction of the speculum — and when, indeed, should the phalloid instrument be neglected, if the patient be a female!—let us by all means have recourse to some other medium of communication between the patient and doctor — some new instrument of legitimate medical charlatanry—that may strike, if not amuse or gratify, the former, and recommend the latter. How is it that, amid the remarkable number of spine-doctors and writers on spinal curvatures for the benefit of a discerning public, no one has invented a pocket instrument for examining and straightening the spine? Or, has one been actually invented, but, having been always applied *à posteriore*, no one besides the inventor and manipulator has yet been able to detect the excellence or penetrate the mysteries of the invention?

16. II. THE CAUSES OF DISEASES OF THE SPINAL COLUMN, MEMBRANES, AND CHORD, are generally sufficiently manifest; but they are occasionally more or less obscure, especially as regards the extent of their individual influences. As the causes of disease of the several structures composing the spine are almost common to each variety or form of malady to which these structures are liable, although certain of the causes affect one tissue in preference to the others, I shall, therefore, devote a due consideration to all of them, with such notices of their effects as may best subserve practical purposes.

17. *A. Improper physical education and clothing* comprise a great variety of circumstances and causes productive of curvatures, and even of more acute disease of the spinal column; and, although this class of causes operate chiefly in childhood and early life, yet their effects often continue until old age, and are rendered more severe and irremediable by the regimen and clothing adopted during puberty and adult age. In this climate more especially, the frequent and sudden vicissitudes of temperature and humidity require that the body—both trunk and extremities—should be covered in such a manner as to preserve the surface in a sufficiently warm and perspirable state, avoiding any excess or extreme of cold or warmth, and to allow a free and easy exercise of all the muscles of the extremities and trunk. Thus clothed, and avoiding all cinctures or corsets, or other baneful contrivances introduced by ignorant dogmatisers, from the period of infancy upwards; exercise in the open air and in sunshine; sufficient but not immoderate or improper food, are the means which will best ward off affections of the spine, and in proportion as either of these is neglected, so will a predisposition to these affections be generated.

18. The use of stays or corsets of any kind during childhood, and exposure of the joints to cold, are amongst the greatest evils to which the human race is liable. The former embarrasses and limits the actions of the dorsal and lumbar muscles, and of all the muscles of the trunk, weakens and relaxes the vertebral ligaments, and whilst it favours unnatural curvatures, endangers more or less the important parts lodged in the vertebral canal: the latter weakens and enlarges the joints, and depresses vital power. The want of due air and proper exercise from the age of five years to twenty; the mental cramming pursued during the greater part of that time; the prolonged periods of study in a crowded and insufficiently ventilated apartment; sleeping in a self-contaminated air, and in chambers overcrowded or too small for the number of occupants; insufficient, or unwholesome or incongruous food, are very generally associated causes of the delicacy of constitution, of the weak or imperfect development of muscle, and of the relaxation of ligaments, which both predispose to, and even directly occasion, spinal curvatures and disease. The vice of self-pollution, moreover, which is apt to spring up and diffuse itself in young persons about the age of puberty, when they live in considerable numbers under one roof, remarkably aid these causes in developing their effects upon the nervous system and spinal column; but to this most important agency more particular attention will be paid in the sequel.

19. In connexion with the use of stays, the usual mode of their construction requires some notice. Whilst they are so made as to press downwards and together the lower ribs, to reduce the cavity of the chest, especially at its base, to press injuriously upon the heart, lungs, liver, stomach, and colon, and even partially to displace these vital organs, they leave the upper regions of the chest exposed—those very regions where tubercular, consumptive, bronchial, and inflammatory diseases generally commence, or are the most prone to attack—to the vicissitudes of season, weather, temperature, humidity, and external injury. These noxious and unnecessary articles of clothing — these mischievous appliances to the female form, useful only to conceal defects and make up deficiencies in appearance, are rendered still more injurious by the number of unyielding, or only partially yielding, supports with which they are constructed on every side. There are the whalebones in the back and sides, and the steel in front, extending from nearly the top of the sternum almost to the pubes. The motions of the trunk and

spine are thereby restrained, and the nutrition of the compressed parts impaired; but, irrespective of the displacement of vital and assimilative viscera that follows the amount of pressure, the metal support in front has an injurious effect, which has been universally overlooked. However well it may be protected from contact with the surface, it acts as a conductor both of animal warmth, and of the electro-motive agency passing through the frame: it carries off by its polarization, into the surrounding air, especially during humid states of the atmosphere, the electricity of the body, this agent being necessary to the due discharge of the nervous functions, either in its electro-galvanic, or magneto-electric, state or manifestation. The injurious influence of stays on the female economy, as respects not only the diseases of the spinal column, but also the disorders of the uterine organs, is manifest to all who consider the subject, and has been ably discussed in a work by Mr. Whitfeld of Ashford, to which I refer the reader.

20. *B. Constitutional vice and diathesis* especially favour the occurrence of, and even directly occasion, diseases of the spinal column. Of these the most influential are the scrofulous, the rheumatic, and the cancerous. Scrofula, either latent or developed — whether concealed or tuberculous — often produces disease of the bodies of the vertebræ, either in the form of scrofulous inflammation of them, or by infiltrating their cancellated structure with tubercular matter. The *causes of scrofula,* fully discussed in another place (see *art.* Scrofula, §§ 13. *et seq.*), have in many instances the effect of developing disease of the spine without having previously changed the diathesis or habit of body, at least in an obvious manner. In such cases, they are often only predisponents to such disease, some other agencies exciting it. Whilst scrofula chiefly causes disease of the vertebræ, the rheumatic diathesis, or pre-existing rheumatism, favours the occurrence of rheumatic inflammation of the ligaments of the spine, or rather of the sheath and membranes of the chord. Inflammation of these tissues may appear either as a metastasis of the rheumatic attack, or primarily upon exposure to cold or wet, or to currents of cold air in this quarter. The gouty diathesis is not so frequently a cause of spinal affections as rheumatism; but congestion of the venous sinuses of the spinal canal, causing pain in the back and loins, and feebleness of the lower extremities, is a frequent complaint in gouty persons. The cancerous diathesis has probably little influence in the production of spinal complaints, although the several varieties of cancerous disease have been occasionally found to implicate one or more of the spinal structures. Children, whose parents are aged or debilitated, and whose conformation is originally weak; the progeny also of the dissipated, the drunken, or the exhausted by syphilis, mercurial courses, or cachectic affections; a rapid or premature growth, and children brought up by hand, or living in large towns without the advantage of occasional change of air; are much more liable to spinal affections, than others differently circumstanced, as they advance in growth or age.

21. *C. Certain previous maladies,* especially those above-mentioned, exanthematous and malignant fevers, more particularly scarlet fever, the syphilitic cachexia, tuberculous disease, sexual and urinary affections, particularly in the female, aneurisms of the aorta, and internal tumours and abscesses, either favour the development or excite disease of the spine, or of its contents. Aneurisms of the aorta, and internal tumours and abscesses in some instances, by their size and pressure, occasion erosion or ulceration of the bodies of the vertebræ. Flexures of the spine and disease of the vertebræ frequently follow the more severe attacks of the exanthemata; and tuberculous disease with caries of the vertebræ, sometimes followed by abscess, is frequent not only in the scrofulous diathesis, but after tuberculous affections have been developed in the lungs, mesenteric glands, or in other parts.

22. Uterine irritation and excitement, and the several forms of hysteria, and their numerous manifestations and alliances, are often followed by congestion of the venous sinuses of the vertebral canal; by what has usually been called spinal irritation, or inflammatory congestion or irritation of the chord and its membranes; and by flexures of the spine or structural change of the contents of the column. Frequent sexual excitement and consequent exhaustion, alternating with unnatural rapidity, are the most frequent causes not only of these uterine and hysterical disorders, but also of the allied affections of the spine and its contents: and, although the one class of disorders is generally consecutive of the other, the spinal diseases with their several sympathies more commonly following the sexual, the former may be primarily manifested, especially in the male sex; masturbation about the period of puberty, and premature or excessive sexual indulgences, being the most common causes of chronic disease, the most injurious of vices, mentally and physically, and, whilst they most powerfully predispose to, they directly occasion, especially in weak constitutions, and when aided by other causes, one or other of the more serious maladies of the spine and its contents. (See *art.* Pollution.)

23. *D. The influence of physical agents,* especially of cold, currents of cold air, unusual increase of temperature, more particularly if these be applied to the back; sleeping in damp beds or upon the ground, or in the open air, with exposure of the back; sitting in wet or damp clothes; exposure of the back or loins to much heat, especially during dinner; sudden suppression of the perspiration by exposure to cold or to cold air, as when a person is called out of a warm bed. A medical man was called out of bed when perspiring freely, and got into an open carriage insufficiently protected, during a cold night. He was soon afterwards seized with inflammation of the membranes of the spinal chord. I attended him with other physicians. A corpulent female of middle age slept with her back to a window which had been left partially open. She complained of chills, pains, and rigors, during two or three following days, subsequently of acute pain in the loins, pain, numbness, and cramps in the lower extremities, and other symptoms of inflammation of the spinal membranes. She afterwards became paraplegic. A gentleman from Jamaica, after a hot day, fell asleep at night on the deck of the ship in which he was making his passage to Europe. He awakened cold, shivering, and benumbed, and was soon afterwards generally pa-

ralysed. A gentleman dined at a party where he was a stranger, and did not complain of the heat of the fire at his back. The following day and the next he had frequent vomitings, violent pain in the back and loins, numbness, pain, and cramps in the legs, obstinate constipation and retention of urine, followed by paraplegia. I could adduce numerous instances similar to the above which have occurred to me during a practice of upwards of thirty years. The causes which I have mentioned under this head, as well as those which follow the next to them, generally affect primarily or chiefly the membranes of the spinal chord, the affection of these and its consequences generally implicating more or less the chord itself and the origins or roots of the spinal nerves.

24. *E. The metastasis and suppression of external disease or accustomed discharges* have been partially noticed above. During an early period of my practice, I observed several cases of this occurrence, chiefly at the institutions to which I was physician. In one case of metastasis of rheumatism to the spinal membranes which I treated in 1820, general palsy supervened, and I had an opportunity of minutely examining the spine and its contents after death (*see Lond. Med. Repos.*, vol. xv.). Since that period similar cases have come under my observation, which have terminated either in paraplegia, or in general palsy and death. Suppression of the catamenia, the stoppage of profuse leucorrhœa and of hæmorrhoids, the drying up of accustomed discharges, the healing of chronic ulcers and cutaneous eruptions, have severally been followed by disease of the spinal contents. In many of such cases the blood has been more or less impure—has been insufficiently depurated by the several emunctories; and when the manifestations of this morbid condition have been suppressed in quarters which served as safety valves from more dangerous consequences, they have broken out in other surfaces and parts, and been followed by much more serious results; and although the spinal membranes and chord may not be frequently thus consecutively assailed, yet they are occasionally, when the suppression of the primary disease has taken place before the blood has undergone depuration by an increased action of the excreting organs. We frequently observe surgeons endeavouring to cure eruptions, ulcers, chronic discharges, &c., by lotions, ointments, cerates, and other appliances, either unsuccessfully or with the contingent result of consecutive internal disease when they succeed; whereas, a decided action on the several excreting organs, by appropriate means, by removing effete or injurious elements and materials from the blood,—by counteracting or eliminating those irritating and self-contaminating matters perpetuating or causing the primary disease,—would most speedily and effectually remove it, and prevent any subsequent risk from metastasis or other morbid manifestation.

25. *F. External injuries* are amongst the most common causes of disease of the spine, or of its contents. These injuries may be so slight as to be overlooked or forgotten, their effects being developed slowly and insidiously until they arrive at a pitch which alarms either the patient or his medical attendant. The more severe injuries by which a vertebra is broken, or its intervertebral cartilages torn, or ligaments or muscles ruptured, and the chord or its membranes either more or less injured at the same time, or consecutively affected by inflammation, effusion, &c., readily account for the great extent and danger of the effects produced. But there are slighter injuries, which sometimes slowly, and after a protracted period, occasion no less serious results. A slight fall on the back, as on descending a stair, or a fall backwards, when the back, or even the os coccygis, strikes against a hard or sharp substance, is sometimes followed, if due care be not taken, by serious effects—by inflammation of the membranes of the chord, or even of the chord itself, and, if not rationally treated, and even when so treated in faulty constitutions, and if a proper regimen be not adopted, by paraplegia, often passing on to general paralysis, and ultimately terminating in coma and death.

26. Concussions of the spine occasioned by falls, or by leaping from great heights or other modes, are frequently followed by effects usually produced by the most severe injuries of the column, even although no fracture, rupture, or dislocation can be traced. The vertebræ and intervertebral cartilages may nevertheless have sustained some injury, and the minute organization of the chord and the origins of the nerves may have been ruptured or injured so as to escape detection after death upon a superficial inspection. In these cases, the severity of the effects will lead to a due appreciation of the importance of the cause. But a slight effect should not be unheeded; and even the most trivial symptom, apparently to the uninstructed or inexperienced, ought to attract to itself marked attention and care. Several instances have come under my care where the most dangerous and even hopeless consequences have followed the slightest falls and concussion, the more immediate effects having failed to attract the attention or care of the sufferer.

27. Amongst the less marked causes of disease of the spine or of its contents, although occasionally productive of the most important results, are muscular efforts in lifting heavy bodies, or similar efforts made suddenly or irregularly, and when volition is not duly exerted, or is directed also in a different direction. Rapid movements, torsions or bendings of the spine; undue pressure made upon one side of the vertebral bodies, by unnatural positions retained for a long time; frequent rotations of the column, and reaching to objects too high or too low, are occasionally productive of injurious effects. The most fatal injury may even follow a common or slight effort. A strong muscular man broke the second vertebra of the neck completely across on both sides when pressing his head on the pillow as a fulcrum to enable him to turn in bed, and the nature and extent of the injury were ascertained after death by Professor Quain and myself.

28. Curvatures of the spine often result from assuming the same position on frequent occasions —by sleeping on a high pillow on the same side, by improper postures in writing, playing on the harp or guitar, by drawing, by carrying a weight or burden on the same arm, as in nursing, and by always using one hand more than the other. Riding on horseback produces most injurious physical and moral effects on females: it gives the spine a certain degree of twist; and the concussions im-

parted to the nates, pelvis, and trunk, occasions a degree of excitement followed by exhaustion, which, if not amounting, often leads on, to self-pollution. To these apparently slight causes, especially to their continuance, the lateral curvatures of the spine, so very frequent in females, are in great measure to be attributed.

29. III. CURVATURES OF THE SPINAL COLUMN, — FLEXURES OF THE SPINE, — LATERAL CURVATURES OF THE SPINE,—*Lateral Deflections of the Vertebral Column*; — *Unnatural Deviations of the Spine.—Distortions of the Spine.* — *Functional Curvatures of the Spine.*

30. CLASSIF.—I. CLASS. IV. ORDER (*Author in Preface*).

31. DEFINIT.— *Unnatural curvatures of the vertebral column, occurring from other causes than from structural changes of the bodies of the vertebræ.*

32. Curvatures of the spine, produced otherwise than by caries or anchylosis of the vertebræ, may be divided into three *varieties or forms*, namely, *posterior curvature*, or excurvation, the convexity being directed backwards or outwards; — *anterior curvature*, or incurvation, the convexity being inwards or anteriorly;—and *lateral curvature*, the convexity being to either side, generally the right, and, when considerable, being either double or complicated. The angular projections occasioned by caries or anchylosis of the bodies of the vertebræ are altogether different in their natures from these curvatures, and fall under a different category of lesions.

33. i. POSTERIOR CURVATURE OF THE SPINE, — *Excurvation*, — *Cyphosis*, — affects chiefly the dorsal and cervical portions of the spine, and only occasionally extends to the upper lumbar vertebræ. It is often caused in infancy by the common practice of raising the child by the open hands placed under the arm-pits, whereby the ribs are pressed inwards, and the spine and sternum are pushed outwards, as described when treating of *deformities of the chest* (see *Art.* CHEST, §§ 2. *et seq.*), where the causes producing it are fully stated. Slighter forms of this curvature occur in young persons, and in adults, owing to shortness of sight and the habit of stooping, and holding the head near objects when reading, writing, or working; and in aged persons from diminished thickness and elasticity of the intervertebral cartilages, and in these the curvature extends lower in the spine. When the curvature is considerable, the anterior portion of the ring or body of each vertebra is rendered somewhat thinner or more flattened, especially in the centre of the curvature, —and, as a necessary consequence, the transverse processes, and still more so the spinous processes, are more separated. The ligaments are also affected, the posterior being more or less stretched. When the ribs are laterally compressed, so as to diminish the diameter of the chest from right to left, the sternum is pushed outwards, assuming a similar position to the dorsal spine. In other cases, the sternum follows the direction of the dorsal vertebræ, the ribs being curved outwards, and the diameter of the thorax being lessened between the spine and sternum. If the excurvation implicate the lumbar vertebræ, the angle formed by this part of the spine with the direction of the sacrum or pelvis is lost, and the brim of the pelvis becomes horizontal, the spine and the direction of the pelvis being in nearly the same axis. In excurvations of the spine, the capacity of the thoracic and abdominal cavities, and the position of the viscera, are more or less affected, the former being diminished, the latter being somewhat changed or embarrassed.

34. ii. ANTERIOR CURVATURE, — *Incurvation of the spine*, — *Lordosis.* — This form of spinal curvature is most rare. It is most frequently met with in a slight form in the lumbar vertebræ, and is then merely an exaggerated state of the curvature natural to this part of the spine, and is seen not infrequently in persons who, in early life, have brought their lumbar muscles into very active use. In other circumstances, however, it is occasionally observed giving the abdomen unusual prominence, and, when seated near the pelvis in females, presenting the appearance of pregnancy or of ovarian disease. When this curvature affects the dorsal vertebræ, it occasions marked deformity of the chest: the posterior angles of the ribs pass outwards and backwards from the spine, and the antero-posterior diameter of the thorax is diminished, unless, indeed, the sternum be also pushed forwards, which is rarely the case. When the anterior curvature is seated so low down in the lumbar region as to form an angle with the sacrum, the effect in females during parturition may be serious, as it is frequently connected with a diminished antero-posterior diameter of the brim of the pelvis.

35. This form of curvature may arise from an increased force, or more frequent and developed action, of the dorsal or lumbar extensor muscles, relatively to the vital tone or cohesion of the anterior ligaments of the spine, and to the action of the recti abdominal muscles; and it may be associated with some constitutional taint or disease, as with scrofula, rickets, syphilis, or some cachectic condition, &c. When it is connected with rickets, it is most apt to occur during convalescence from this malady.

36. iii. LATERAL CURVATURE. — *Lateral deflections of the spine*,—*Scoliosis.*—This is by far the most common form of spinal curvature; and generally appears between the ages of 10 and 18, although it may commence either earlier or later. It is most common in the upper and middle classes, and comparatively rare in the lower or harder working orders. Owing to the position of the viscera—to the heart on the left, and the liver on the right, it has been supposed that there is always a tendency to a double lateral curvature of the spine, especially in lymphatic, weakly constituted, and cachectic persons. There can be no doubt that, whatever influence may be produced by this circumstance, it is really so small as not to deserve consideration. The upper lateral curvature has generally its convexity to the left, is small, and comprises the lower cervical vertebræ with two or three dorsal vertebræ. The second or middle curvature is the most remarkable; has generally its convexity to the right, and is formed by the dorsal vertebræ. The third or lower curvature has its convexity to the left, and comprises the lumbar, and lowest dorsal vertebræ. The first or upper curvature may be very slight or altogether wanting, although the second or dorsal is considerable; but, in this case, this latter extends higher, and the third or lumbar is also considerable. Either the dorsal or lumbar may

be the most marked, more frequently the former, which, in some instances, may appear the chief or only one.

37. Lateral curvatures may be very slight, or they may be very great: they are seldom completely lateral, but are commonly conjoined with more or less posterior curvature. It is manifest that, when the deflections of the column are very considerable, the natural rotation of each vertebra on the other must be diminished or limited in the curvatures, and that it must take place chiefly between them, or between those vertebræ which remain the nearest to the natural axis of the trunk. The sides of the bodies of the vertebræ must also experience greater pressure towards the centres of the concavities and diminished pressure at their convexities: hence will result compression of the more yielding tissues and impaired rotation at the more flexed situations. The intervertebral tissues are first compressed in the sides, which are concave, and afterwards thinned. The bodies of the vertebræ are also more or less affected, and atrophied in these sides, and assume somewhat of a rhomboidal form. The articulating processes are much altered in the situations where the curvatures are greatest: they are atrophied, nearly obliterated, and absorbed in the concavities; and rendered more prominent, the spinous processes being also more protruded, in the convexities.

38. When lateral curvatures are very great, the effects become still more serious. The passages between the vertebræ for the nerves and bloodvessels are straitened and almost obliterated in the concave side, and enlarged and elongated in the convex. The consequences of the constriction of these outlets must be evident in respect of both nerves and bloodvessels. They were pointed out by MORGAGNI and PORTAL, and more recently insisted upon by CHAILLY and DUGES. The pressure, also, on the sides of the vertebræ sometimes causes partial absorption or caries of the part which suffers the most from it; and, in these situations, or where the concavity is greatest, ossific deposits are there formed, producing partial or lateral anchylosis, sometimes extending to the lateral, transverse, or oblique processes of articulation, and furnishing support to the most affected and weakened part of the spine. In these situations the ossific formation results from a state of chronic inflammation which is productive of this work of reparation.

39. The *consequences* of extreme or even of considerable lateral curvatures are often very serious. The patient is liable to severe pains, cramps, numbness, and impaired action of the muscles supplied by nerves issuing from the concave side of the spine, when the passages for the nerves and bloodvessels are narrowed. Emaciation frequently follows; and owing to the falling inwards and approximation of the ribs on the concave side of the curvature, and to the bulging outwards of those on the convex side, the cavities of the chest and abdomen are rendered more or less irregular or unsymmetrical, and are also much encroached on; the viscera, especially the lungs and heart, and even the liver, kidneys, and alimentary canal, are embarrassed or impeded in their functions; difficulty of breathing, amounting sometimes to orthopnœa, and palpitation, or slowness, or irregularity of the pulse often occurring, with a feeling of incapability of raising the ribs, or of taking a full inspiration, especially on the concave side. Frequently the viscera accommodate themselves to their unnatural position, when the curvatures increase gradually, and comparatively little inconvenience is experienced unless upon increased exertion; but, when these viscera, particularly the heart or lungs, are attacked by disease, to the causes of which their physical and vital conditions render them most susceptible, then the consequences are much more serious than when these organs are attacked in different circumstances.

40. It is very rare for the spinal chord or its membranes to experience much disorder during lateral curvature, unless the bodies of the vertebræ at the place of greatest concavity become inflamed or carious; but, when either of these results ensues, chronic inflammations, effusions, and organic changes occasionally supervene, in the parts contained by the diseased vertebræ, and the usual effects, namely, severe pain, spasms, and contractions of the muscles of the trunk and extremities and loss of motion, with or without loss of sensation, generally take place. The disease of these structures sometimes extends until the greater part of the spinal contents is invaded, and even until inflammatory action reaches the membranes of the brain, and occasions effusion within the cranium, coma, and death.

41. When the deviation is great, deformity is manifest as regards the position of the shoulder-blades, the collar-bones, and the pelvis. The muscles are also affected, those which are the least used becoming pale and atrophied; and the ribs are also more or less distorted, those on the concave side not merely being closely approximated, but, in old and extreme cases, becoming partially anchylosed. The chief curvature implicating the dorsal spine commonly presents its convexity to the right, pushing outwards the shoulder-blade, and causing the left shoulder-blade to fall inwards. When the chief curvature is in the lumbar region, it is generally directed to the left, and more or less posteriorly, the bodies of the vertebræ being considerably changed (§ 37.), and sometimes becoming even disorganised.

42. *The progress* of spinal curvatures is extremely variable. They sometimes proceed slowly and insensibly; occasionally rapidly. They have been said sometimes to occur suddenly and unexpectedly after a first confinement, and increase remarkably. It may be suspected that in such cases, the curvature had existed previously, but had been concealed by the dress; the puerperal states and lactation merely augmenting the deformity. Curvatures may proceed to a certain extent, and become stationary ever afterwards; or they may, upon the removal of the causes, and by proper means, be in great measure remedied. When neglected, they may be increased so as to bend the patient forwards or to either side, in a most surprising manner, the arm-pit almost reaching the hip-joint.

43. iv. The PROGNOSIS OF CURVATURES depends chiefly upon their extent, and upon the effect produced upon the spinal contents, upon the spinal nerves, and upon the viscera of the chest and abdomen. The curvature may be very great, and yet, as long as neither spasms, nor paralysis, nor marked embarrassment of the functions of vital or internal organs, nor other serious disorders,

supervene, reasonable hopes may be entertained of an advanced age being reached. The appearance of such disorder, as a manifest consequence of curvature, should suggest an unfavourable prognosis; the danger having stricter reference to the nature and extent of the consecutive disturbance, than to the amount of curvature. The removal of old curvatures is seldom attained with complete success; and, unless with the view of alleviating serious disorder occasioned by them, should not be rashly attempted; for adhesions, adaptations of parts, ossific formations even, and other alterations, may have taken place, that may not be disturbed, without occasioning more serious disturbance.

44. v. THE CAUSES which more especially occasion curvatures of the spine are the female sex; the age between 9 and 18; a lymphatic, scrofulous, or ricketty constitution; an originally weak conformation of frame; an exhausted, feeble, or cachectic habit of body; insufficient food, living in low, humid, and close situations, and all the causes productive of scrofula; convalescence from acute and chronic maladies; want of pure air, light, and sunshine; a premature and rapid growth; defective or improper exercise; crowded and close apartments during night and day; the continuance of mal-positions; the too exclusive use of the right hand and arm; the use of stays and metal or other supports, and self-pollution. MAYOW attributed curvatures to a want of harmony between the development of the vertebral column and that of the muscles; and MORGAGNI, MÉRY, and more recently GUÉRIN, believed that they are often caused by contraction of the muscles consequent upon disease of the nervous centres. MAYOW's hypothesis is incapable of support; the opinion of MORGAGNI is more deserving of attention, and may be admitted to be just in some instances.

45. vi. THE TREATMENT OF SPINAL CURVATURES, as promulgated to the public in recent times, would, in the hands of a MOLIÈRE, furnish a most bitter satire on medical practice:—so many writers, and so much said, and yet so little information furnished,—each successive author depreciating the means advised by his predecessors, and yet adding nothing to what was already known,—every new spine-doctor having his own apparatus, instrument, or couch to recommend and to sell, either or both being said to be capable of curing cases which were heretofore incurable, —the parading of casts of deformed trunks, rendered as symmetrical as the statues of antiquity by the newly discovered or peculiar method of treatment —the publication of books, containing merely exaggerated accounts of successful cases, without even, as in some of these publications, any notice of the methods employed,—the promulgation of opinions opposed to anatomical and physical truths to subserve delusion,—and large promises, but scanty performances, were amongst some of the means adopted by the majority of those who had chosen this *speciality*, as the best calculated to fulfil the objects of their professional mission. But it may be as well to take a brief view of the methods lately promulgated, and of the progress made (?) in this department of medical practice.

46. Mr. BAYNTON, in 1813, advocated rest for a long time in the horizontal position, on a specially constructed couch, but furnished no particulars of treatment.—Mr. SHELDRAKE in 1816, recommended an instrument of his own to support the weight of the head; and extension on an inclined plane, &c.—Mr. WILSON, in 1820, advocated chiefly muscular exercise directed especially to the dorsal muscles, the horizontal position occasionally; and he justly condemned all instruments which are made to act from the pelvis upwards, and which were then much in vogue among distorsion-curers.—Dr. JARROLD, in 1823, considered curvatures to depend upon constitutional causes, treated them accordingly, and prescribed chiefly muscular exercises, burnt sponge and carbonate of soda internally.—Mr. BAMPFIELD, in 1824, advised muscular exercises, extension of the spine by pulling the legs and arms, frictions and shampooings, and the use of instruments to exercise particular parts.—Dr. DODS, in 1824, objected to the inclined plane, to any spinal apparatus, and to the practice of carrying weights upon the head, as directed by some of his predecessors. He employed a concave couch to bend the whole spine forwards, and to relax the spinal muscles. The success of this plan must have been astounding! — Mr. JOHN SHAW, in 1827, resorted to muscular exercises, to supports for the spine, and to extension on a couch of his own contrivance. — Dr. HARRISON, after publishing numerous cases of vaunted success, and withholding any account of the means employed, produced, in 1827, a large book, which contained nothing but unsound views, exaggerated accounts, and a mystification as to his method of treatment. This, however, was nothing more than the horizontal position on a fixed mattress, friction, &c. This last he directed by means of assistants in such a manner as to lead his victims to persevere, and to inspire them with hopes which were rarely realised.—Mr. STAFFORD, in 1832, advised spinal supports, the horizontal position, conjoined with exercises.—Mr. BEALE, in 1833, recommended frictions, muscular exercises, mechanical extension, and instruments in certain cases.—Mr. COULSON, in 1839, prescribed suitable exercises, and condemned, with great justice, all kinds of collars, machines, or instruments.—Mr. WARD, in 1840, resorted to the recumbent position, to exercise of the muscles of the spine and head, and objected to mechanical supports.—Mr. TUSON, in 1841, advocated principally the recumbent position on a couch of his own contrivance, that admitted of muscular exercises while recumbent.—Mr. C. R. HARRISON, in 1842, published his work to say, that he cured deformities of the spine and chest by exercise alone, and without extension, without pressure,—the means empirically employed by his late namesake,—and without division of muscles — the division of muscles having been then brought into vogue from Germany, the fruitful parent of humbug, for curvatures, for squinting, and for every thing to which credulous fools would submit.—Mr. HARE, in 1844, wrote to recommend his couch, which acted on the spine by extension produced by pulleys and weights.—Mr. COLES, in 1845, praised the prone position, for which he constructed a couch on which the patient reposed upon his chest and abdomen, with exercise of the muscles of the spine and upper extremities.—Mr. TAMPLIN, in 1846, confided altogether in mechanical support by

means of a steel instrument, which he contrived for this purpose, based, like many of those employed by the instrument makers who had gone before him, to rest upon the pelvis. He condemned the horizontal position and all kinds of couches.—Mr. **Lonsdale**, who has furnished me, in his work, with a portion of the above information, in 1847, improved greatly on Mr. **Tamplin's** instrument, adding its best and most original part, and recommended a couch which appears to be the best of all hitherto employed.

47. From this exordium, the reader will perceive the amount of information to be obtained from books, each one of which is written to recommend the practice adopted by its author to the notice of a "discerning public." Physicians are now-a-days allowed to have nothing to say to, far less to do with, this very notable "speciality," or indeed with any complaint, respecting which speciality-doctors have enlisted the "sweet voices" of the public. But physicians will nevertheless look on, and even observe closely the results, note the errors committed, mark the subterfuges resorted to, notice the delusions practised, and remark also the credulity, occasionally interrupted by passing visions of the truth, displayed by the victims during the protracted treatment of a spine-doctor. The study all the while is not without interest to the philosopher: the arts and cunning displayed to conceal expected want of success, and to ensure the faith and perseverance of the patient; the resignation of the latter, and the confident dogmatising of the former; the entire surrender of judgment, liberty, and opinion on the part of the devoted sufferer; the "hoping against hope," and the influence gained over weak minds by the assumed confidence, the decided manner and the repeated promises of the reputed deliverer, furnish food for contemplation and instructive illustrations of the constitution of the human mind. In this way, months, and even years, are passed; the submission and credulity of the one keeping due pace with the domination and perseverance of the other — the hopes entertained by the patient, that future success may ultimately compensate for the losses and sufferings and endurance of the past, protracting still further the period of empirical domination, until at last emancipation arrives; and the patient awakes to her condition, and arises with emaciated muscles, impaired strength, and with loss of the use of her limbs. Nevertheless, she may not confess her delusion. The power which had so long fettered her mind and body retains still a portion of its sway; and whilst she feels the bitterness of her delusion, she has no desire to admit her folly or to confess the full amount of its consequences. She consoles herself with the idea, assiduously inculcated by the persevering attendant, that, without the means of which she has been the victim, the deformity might have been much worse, and with thankfulness for this assurance, she submits to her fate, until another "unfailing method of treatment" excites her attention, when the desire of recovering her shape or of preventing extreme deformity again induces her to enter upon another protracted period of penance, the means being different but the results the same as heretofore.

48. Now, after the numerous repetitions of the means enumerated above, — after the endless variations, modifications, combinations, denunciations, &c. which the very imperfect list just furnished presents — what can I have to recommend, who have seldom had to deal with such cases, unless in rare instances when I have considered it right to interfere to prevent the dangerous consequences which would ensue, or were actually ensuing from a vicious system? What I therefore advise may be briefly enumerated in the following categories: —

49. *A.* To ascertain the several, and especially the chief causes of the curvature, extrinsic or physical, intrinsic or constitutional, mental or moral; to endeavour to estimate correctly their individual influences; and to direct a decisive and scrutinising inspection on their energetically inculcated removal and avoidance. If only one of the causes of mischief continue in operation the best devised treatment may be inefficacious.

50. *B.* To determine accurately the extent and nature of the curvature, the amount of deformity, and the degree in which it has involved the natural positions of the pelvis, shoulders, the clavicles, sternum and ribs; to ascertain in how far the shape and capacity of the thorax and abdomen are affected; to note the states of the digestive, assimilating, and excreting functions; to examine the condition of the muscular and fibrous structures, as manifested by the muscles of the trunk and extremities, and especially by those of the spine, and by the joints; to detect whatever disorder of the thoracic or abdominal organs the curvature may be associated with; to determine the state of the circulation and of the blood as respects the presence of chlorosis, anæmia, or plethora, and to ascertain the conditions of the uterine or sexual organs; and, having acquired all the information that can be obtained respecting these, and having reviewed this information in connexion with what is known as to the causes, to consider well the indications and means of cure which the whole inquiry may suggest.

51. *C.* Having commenced thus carefully, to put these intentions and means into practice, decidedly but cautiously, and in suitable combinations when such are clearly indicated: — (*a*) To pay strict attention to the restoration of the general health — to attend to the digestive and depurating functions, to the advantages of pure air, ventilation, sunshine, and suitable exercise, both before, and during, the employment of other means directed more especially to the removal of the curvature; and at the same time to have recourse to such tonics and restoratives as will promote assimilation.— (*b.*) To have recourse to instruments only when these are imperatively required, and to select such as will admit of the movements of the spinal muscles, and press upon the convexity of the curve. — (*c.*) If couches alone, or in addition to instruments, in the intervals between having recourse to them, or after due exercise, be absolutely required, to select those which furnish pressure chiefly on the convexity of curvature, and liberate the spine from the pressure and warmth of a supine position; and facilitate a recourse to frictions and other means of restoring the tone of the spinal muscles and ligaments. To each of these I would direct a more particular notice.

52. *D. The restoration of the general health* previously to, and during, a recourse to the more empirical and mechanical means adopted by those who take this particular class of affections under

their generous protection, is too generally neglected. Many of the causes most influential in producing curvature act chiefly by impairing the constitutional powers and the general health — by enfeebling the digestive and assimilating functions, by impeding the excreting actions, by relaxing the tone of the nervous and fibrous structures — and hence the importance of the entire removal of these causes, and of the restoration of these functions to health. Of all the causes of curvature, the most frequent, the presence of which it is the most difficult to ascertain, and the most seldom relinquished when so long practised as to produce this effect, is *self-pollution.* Its effects in exhausting organic nervous power, in emaciating the muscles, and in relaxing the ligaments, are much more remarkable than those of any other cause. Attention, therefore, should always be especially directed to its detection and entire relinquishment.

53. Restoration of the vital functions in spinal disorders should be directed not merely to the functions of digestion and excretion, but also to the conditions of the vascular system and of the uterine and urinary functions. If vascular plethora be not present — a condition which is seldom associated with curvatures — the preparations of iron are generally of service, especially if anæmia or chlorosis also exist. If neither of these be present, bitter infusions or decoctions may be first given, and afterwards the tincture of sesquichloride of iron, with or without a little hydrochloric acid, and the infusion or tincture of calumba, may be prescribed accordingly; but, in cases associated with anæmia or chlorosis, the preparations of iron should be adopted forthwith, especially if the urine be alkaline or contain much of the phosphates; and, in these circumstances, the preparation just named and the hydrochloric acid should be employed, and they may likewise be prescribed if the uterine discharge be great, or leucorrhœa be present. In other conditions, or when the catamenial evacuation is insufficient or obstructed, the sulphate of iron, with the aloes and myrrh pill, or the compound mixture of iron, with a sufficient quantity of the compound decoction of aloes to preserve the bowels freely open, will generally prove most beneficial.

54. *E.* Without due *ventilation, light, sunshine, and exercise in the open air,* short of occasioning fatigue, health will neither be restored nor preserved. Large airy sleeping apartments, the light of heaven, and *exercises* of the muscles of the back and extremities, are the most conducive to the prevention of curvatures, and to the restoration of the health of crooked persons. These persons should never ride on horseback, nor even in a carriage, when either can be avoided. Walking is the best exercise, and next to that such exercises as will moderately engage the muscles of the arms, shoulders, and back. Various modes of exercising these muscles have been recently recommended; but, whatever plan be followed, the muscles of both sides ought to be equally exercised. Certain exercises tend more to *prevent* curvature than to remove it; as the skipping-rope, shuttle-cock and battle-door, the use of dumb-bells, and exercises with the rod. The Indian sceptre exercises described by Mr. WALKER, in his work on "*Exercises for Ladies,*" are the best adapted to the prevention of curvatures and to the removal of those which are slight. When the curvature is more manifest, or even very great, pulleys should be fixed, at a considerable height above the patient's head, with weights attached to them, great in proportion to her age and strength, and in a situation which will admit of their being pulled in either a forward or backward direction. A stand, also, with a cross bar, or with more bars than one, considerably above the head of the patient, may be erected in a suitable open or airy situation; and, by taking a firm hold with both hands, attempts should be made, gently and cautiously at first, to raise the body by the muscles of the arms and shoulders. When the muscular debility is great, it is generally of great service to have recourse to frictions over the muscles of the spine and back with a warm stimulating liniment or embrocation, for some time previously to adopting these exercises. In 1822 the daughter of a friend had for a very long period been cased in metal instruments, and had suffered in health and strength, without any benefit as to the curvatures. I requested the instruments to be thrown aside, directed frictions to the spine and back, at night and in the morning, with the following liniment, and afterwards a gradual and careful recourse to the exercises just described. The cure was rapid, complete, and permanent.

No. 336. ℞ Balsami Peruviani, et Bals. Tolutani, āā, ʒj.; Olei Terebinthinæ, ℥j.; Linimenti Saponis ℥jss.; Olei Cajuputi ʒjss, Olei Olivæ, ℥jss. vel q. s. ut fiat Linimentum, more dicto utendum.

55. In many cases sponging the back with a strong solution of bay-salt, of a tepid warmth at first, and gradually reducing the temperature subsequently, will be of service, and may be employed once or twice daily. The exercises should be carefully directed, used for short periods only, especially at first, and never so long as to cause fatigue. In the intervals between exercise, the patient should assume the recumbent position — either supine or prone, or upon either side — on a firm horse-hair couch, either horizontal, or very slightly inclined, and with a low pillow. If the patient recline on the side, especially on the right side, or on that which presents the greatest convexity, she ought to place a horse-hair pillow under that part, so as to thrust the convexity towards the true axis of the spine, and retain it in that position as long as she can. Sleeping with too high a pillow, and generally on the same side — most frequently the right — often of itself produces slight curvature. In these cases, a different position should be chosen, the pillow ought to be placed under the side just beneath the arm-pit, when that side is reposed upon, and the patient should be induced to employ the arm and hand of the side on which the dorsal concavity exists.

56. *F. The use of instruments* has been very generally advised by both qualified and unqualified persons. They are required only in the more extreme cases of curvature, and at intervals, or only when it is necessary that the spine should be supported or aided in carrying the weight of the head and shoulders. Mr. LONSDALE's spinal support is the best hitherto constructed, inasmuch as it both supports the weight of the upper parts, and presses the convexity of the curvature inwards, or towards the true axis of the spine. The chief objection to this and all other instruments is the material of which they are constructed; for a broad hoop of iron or steel encircling the pelvis as a basis for support and pressure, and the other

metal parts forming the supports, springs, screws, &c., however well they may be padded, not only hamper or restrain the movements as long as they are applied, but also, and most injuriously, act as conductors of the electricity circulating through and on the surface of the body, conveying it into the atmosphere, especially during warm or humid states. The other instruments, which I have seen, besides those just mentioned, are altogether undeserving any notice.

57. G. *Of couches*, it is unnecessary to say much. A common horizontal couch, firmly made with horse-hair, or one very slightly inclined, is all that is required; but it should be well provided with hair-pillows of different sizes; and, when the patient reclines on the side with the dorsal convexity, a pillow should be placed under it in such a manner as to press it upwards; and when she reclines in any other position as well as in this, the pillow under the head should be low, unless, indeed, she attempts to lie on the side of the dorsal concavity, when it ought to be much higher. I have recommended this use of the pillows of the common sofa or couch for upwards of thirty years in the few occasional cases of curvature, which I have been requested to treat for other ailments; and I believe they are used in a similar manner by Mr. Shaw. In the excellent couch constructed by Mr. Lonsdale, a broad belt passes between supports attached to the sides of the couch, and the patient, when reclining, places the belt under the convexity, and has it drawn upwards; the weight of the body being in great part borne by the belt, which thus presses the convexity upwards. Another couch has been employed by Mr. Coles, for facilitating the prone position and exercise with the arms when this position is retained. It is well adapted to posterior curvature or excurvation of the spine, but it should be used with great caution when this curvature is owing to disease of the bodies of the vertebræ, as will be shown hereafter.

58. IV. Spinal Column—Nervous or Painful Affections of the.—Synon.:—Rachialgia (from ῥαχις the spine, and αλγος pain).—*Spinal irritation*, of several modern writers.

59. Classif.—I. Class. IV. Order (*Author*).

60. Definit.—*Pain in some part of the spinal column, generally accompanied by neuralgic or hysterical affections, unattended by fever, or by other indications of inflammation, injury, or structural change of the vertebral column, or of its contents.*

61. Painful affection of the spinal column may be limited to a single point or part, or it may affect more than one part, or extend along a considerable portion of the column. It may be continued, remittent, or intermittent, or even periodic. It may be *nervous* or *hysterical*, *rheumatic*, *gouty*, or *syphilitic*. When the pain is connected with any evidence of inflammation or injury, or structural change, it is merely a symptom of such lesion, and may be inconsiderable, or often not the most prominent symptom. It is generally difficult, and frequently almost impossible to determine, in the present state of our knowledge, the precise seat and nature of the pain which is so severely felt in the spine in nervous and hysterical subjects; but that it is chiefly functional, and intimately connected with pain in other situations, or with some other disorder, are well ascertained facts. How far these may illustrate the nature of true rachialgia will be considered hereafter.

62. i. Description.—The history and description of *spinal irritation* were first furnished by the Franks, under the denomination of *Rachialgia*, and subsequently considered by Nicod, Teale, Brown, Darwall, Tate, Parrish, Griffin, Entz, Ollivier, and Bennett. Most of these writers have viewed the complaint more or less in connexion with neuralgic and hysteric symptoms, and have overlooked some of its other morbid relations. It is generally a consequence of pre-existing disorder, more especially of hysteria, of uterine irritation or disorder, of prolonged leucorrhœa, or of excessive or disordered menstruation, of exhausting discharges, of gout, rheumatism, and several other chronic diseases, attended by debility or nervous exhaustion. It is *characterised* by pain, seated as mentioned above, increased by pressure on the spinous processes in the chief seat of pain, and often accompanied by painful, anomalous or hysterical symptoms in parts supplied with nerves from the seat of pain in the spine.

63. i. *A. Spinal irritation occasioning neuralgia or hysterical affections.*—This is the chief form in which painful affection of the spine presents itself in practice, especially in females, or in weakly constituted or debilitated males. If the reader refer to the article Sympathy he will there find an exposition of the connexion subsisting between the ganglial, sympathetic and spinal nerves, and of the manner in which irritation, undue excitement, or exhaustion, or altered sensibility of any one part of the sensory circle of nervous endowment, may implicate, in some way or other, distant parts, — may induce severe pain, in situations remote from the seat of irritation, or spasm, or various modifications of sensibility, or other anomalous affections. I have shown in various parts of this work, that irritation or other morbid states of parts of the alimentary canal, or of the uterine or sexual organs, or of the kidneys and urinary passages, may be propagated thence to the roots of the spinal nerves, to the chord, and be reflected from these, by either sensory or motive nerves, to internal or distant parts; and that the original seat of irritation may produce these effects, either functionally and without developing inflammatory or other palpable changes, or it may induce these changes, owing to prolonged endurance, to its violence, and to the nature of the exciting causes. (See arts. Chorea, Cholera, Convulsions, Hysteria, Disease, &c.)

64. The remarkable diversity of painful, anomalous and hysterical symptoms attending spinal irritation renders a detailed description of this affection unnecessary. The more prominent features are sufficient for its recognition. The distant symptoms or sympathies are often the only ailments to which the patient has directed attention, or even of which he is cognisant. But the physician, upon hearing of these, immediately infers that the disorder is merely manifested in the extreme ramifications of the nerves; and that it is actually either seated in the origins of these nerves, or that it is transmitted to the gangliated roots of these nerves from visceral or ganglial nerves, or that it has been thus transmitted, in the first instance, but followed, owing to the intensity

or continuance of the irritation, by disease at the origins of the nerves displaying the disorder. He therefore examines attentively the state of the spine, by pressure, percussion, or otherwise, especially at those situations where the nerves supplying the affected parts originate; and he often finds, although the patient has never complained of pain in any part of the spine, great pain in these situations, as well as increased disorder of the distant or external parts, when this examination is being made. Pain, more or less severe in the spine, is also excited by muscular efforts, by a sudden or quick movement or rotation of the spine, or by a jerk or slight concussion, or by taking a false step even in walking.

65. In connexion with the tenderness and pain in one or more parts of the spine, neuralgic pains, spasms or convulsive movements, great tenderness of the surface, sometimes loss or diminution of sensation, occasionally loss of motion or incomplete paralysis, and even, in severe or protracted cases, paraplegia; loss of motion being often more complete in one extremity than in the other, and sensation being but little impaired. When the spinal pain or tenderness is felt in the *dorsal portion*, it is sometimes referred chiefly to one side of the column, generally the left side, and extends to, or is felt only, beneath the left mamma, much more rarely on the right side or in the mamma itself. In these cases it is often associated with hysterical symptoms, with a sense of constriction about the thorax, or with a sense of suffocation, dyspnœa or orthopnœa, pleurodynia, palpitations, or accelerated or irregular action of the heart, spasmodic cough, and various other ailments, which present numerous changes and associations, certain of them ceasing suddenly, others appearing and becoming variously complicated, and often exaggerated by the fears of the patient, or the constant direction of the mind to them.

66. When the lumbar portion of the spine is chiefly affected, then the pains, altered sensibility, spasms, constriction, &c. are complained of in the parietes of the abdomen, or hypogastrium, and pelvis. Numbness, cramps, pains, excessive tenderness, or even more or less complete paralysis in the most severe cases, are experienced in the lower extremities, with constipation, suppression or retention of urine, or irritability of the urinary bladder or uterine organs, disordered menstruation, morbid sensibility of the genito-urinary organs, and occasionally a marked and variable alteration of the state, constitution and quantity of the urine itself.

67. Spinal irritation of the cervical portion is not so frequent as in the situations just mentioned; but it is often connected with a similar affection of one or other of these, especially with the dorsal pain and tenderness. Sometimes the cervical pain rises as high as the occiput, and is then associated with neuralgic pains in the face or neck, with deafness or noise in the ears, difficulty of swallowing, a sense of choaking, loss of voice and even of speech, spasm of the larynx or a state resembling an attack of spasmodic croup, and urgent sense of suffocation, complete aphonia, violent attack of suffocative cough, altered sensibility, or incomplete paralysis of one or both arms, coldness and numbness of one or both hands, pricking sensations, formications, &c., in these extremities, with more or less variability and irritability of temper, and often with several of the other ailments enumerated above.

68. The spinal tenderness in some cases shifts its situation. In these, the sympathetic affections are also changed. In connexion with the symptoms already noticed, the functions of the thoracic and abdominal viscera, and even those of the organs of sense, are more or less disordered, but in various and constantly varying degrees, the seat of disorder depending much upon the portion of spine affected. When the disorder is of a very severe character; when epilepsy, convulsions, amaurotic symptoms, deafness, hesitation or difficulty of speech, retention or suppression of urine, hiccup, vomitings, gastrodynia, obstinate constipation, paralysis, &c. take place, then it becomes a matter of doubt whether or no the spinal affection has proceeded to inflammatory action, or has extended to the base of the brain, or to serious congestion of the spinal veins, with increased serous effusion; and a careful consideration of all the sympathetic and constitutional features of the case is then especially requisite.

69. *B. Rheumatic, gouty, and syphilitic* forms of rachialgia, or painful affection of the spine, especially the rheumatic and gouty, are not infrequent—(*a*). The *rheumatic* occurs chiefly in the rheumatic diathesis; in persons who have suffered previously from rheumatism, and very probably is seated chiefly in the fibrous structures of the spinal column, in the ligaments of the spine, and probably also in the intervertebral structure. It is experienced principally on motion, and in portions of the spine which has been the seat of previous injury, sprain, twist, &c. It is generally diminished by the warmth of bed and by the recumbent posture; and it is often accompanied by several of the sympathetic affections already mentioned; but, when these are severe, and are obviously connected with the seat of pain in the spine—when cramps, numbness, constrictive pain in the muscles, prickings in the extremities, loss of motion, &c.,—then the supervention of inflammatory action, or of effusion, or of thickening of the affected tissues, or of congestion of the vascular apparatus of the spine, should be dreaded, even if not actually existing.

70. (*b*). *Gouty rachialgia* is common in old gouty subjects; affects chiefly the lumbar region; is often attended by weakness or impaired motion of the lower extremities, by incontinence of urine, and by other disorders of the urinary organs, or of the urinary secretion itself, varying with the duration and amount of the spinal affection. Gouty rachialgia is chiefly to be referred to congestion of the venous sinuses of the vertebral canal; this congestion probably inducing an increased fluid effusion, with thickening of the ligaments and fibrous tissues of the vertebræ external to the canal; the functions of the chord, or roots of the nerves, being thereby more or less embarrassed.

71. (*c*). *Syphilitic rachialgia* sometimes occurs in the secondary or tertiary stage of syphilis. It may affect the bodies of the vertebræ, or the intervertebral structures, or the ligaments; but it is very doubtful whether or no it exists as a purely nervous affection in the course of this constitutional malady, before these structures are attacked by the changes characterising the advanced progress of this malady. The portion of the spine most frequently attacked by syphilitic lesion, ac-

cording to my experience, is the cervical, the spinal lesion appearing to me to have been an extension of the alterations which had taken place in the throat and pharynx.

72. (*d*). *Scrofulous rachialgia* may be referred to slow inflammatory change, or to tuberculous deposits, in the bodies of the vertebræ; and hence it, as well as the syphilitic, hardly falls under the present category, but comes more legitimately under the head of *disease of the bodies of the Vertebræ.*

73. ii. The DIAGNOSIS of spinal irritation, or pain in the spine, appearing independently of inflammatory or structural lesion, is by no means so easy as several recent writers appear to believe. Whether the painful affections of the spine are the chief disorder, or are attended by various symptomatic disorders of a more prominent character even than their parent affection, they often so nearly approach the milder grades of inflammatory action, in some one or more of the tissues of the spine, that a precise line of demarcation can hardly be drawn between them. An affection which may be, with much justice, viewed as functional to-day — as spinal irritation merely — may be inflammatory on the morrow, and be rapidly followed by the consequences of inflammation. Or a case may occasion apprehensions of inflammation, and yet, as respects its progress and treatment, prove functional merely; whilst another, furnishing less serious grounds of apprehension, may have been actually inflammatory, and soon furnish undoubted evidence of the usual results of inflammation.

74. The diagnosis between functional and structural rachialgia requires a most attentive consideration of all the circumstances of the case, after a careful examination of the spine, and of the whole extent of constitutional and symptomatic ailment. Messrs. GRIFFIN, who have written with much ability upon this affection, have given the following indications of its existence, especially in its nervous or hysterical form:—"1st. The pain or disorder of any particular organ being altogether out of proportion to the constitutional disturbance. 2nd. The complaints, whatever they may be, usually relieved by the recumbent posture, always increased by lifting weights, bending, stooping, or twisting the spine, and among the poor classes often consequent on the labour of carrying heavy loads, as in drawing water, manure, &c. 3dly. The existence of tenderness at that part of the spine which corresponds with the disordered organ, and the increase of pain in the organ by pressure on the corresponding region of the spine. 4th. The disposition to a sudden transference of the diseased action from one organ or part to another, or the occurrence of hysterical symptoms in affections apparently acute. 5th. The occurrence of fits of yawning or sneezing, which, though not very common symptoms, yet, as scarcely ever occurring in acute or organic diseases, may generally be considered as characteristic of nervous irritation." (*Op. cit.* p. 214.)

75. These may be viewed rather as aids to the diagnosis of this affection than as establishing its existence independently of inflammatory action; for many cases, which have been viewed merely as functional, although presenting some degree of prominence of the spinous processes, in the seat of tenderness, certainly are attended by more or less inflammatory action, or congestion, with swelling of the vertebral tissues, the local changes being insufficient to cause very manifest constitutional disturbance, or to disorder the vital and excreting functions. When, however, these are disordered, the existence of inflammatory action or congestion should be suspected. In all cases presenting swelling or prominence in any marked degree, it will be safer to view this as a result of a mild and slow form of inflammation or congestion, or inflammatory congestion, with slight effusion, than to consider the disorder as merely nervous. (*See the description of disease of the Vertebræ.*)

76. iii. The DURATION AND PROGNOSIS of spinal irritation require but slight notice. — (*a*). The *duration* of this disorder is most variable. It may be only three or four days, or as many months, or even as many years, according to the severity, the causes and the treatment of individual cases. There is every reason to infer that the more obstinate cases, especially where the treatment has been judicious, is perpetuated either by the continuance of their causes, or by a chronic or recurring inflammatory congestion of one or more of the tissues of the spine.

77. (*b*.) The *prognosis* of this affection is generally favourable, where it is purely nervous or functional. But, when it is attended by phenomena, local and constitutional, indicative of any degree of inflammatory congestion, the several contingencies of such disorder, as respects both the vertebræ and the spinal contents, should be kept in view, and a more cautious or guarded prognosis be given. When rachialgia occurs in connexion with rheumatism, or gout, or scrofula, or syphilis, a much less favourable prognosis ought to be given, than when it is more purely nervous, or simply congestive or inflammatory. In the rheumatic variety there is danger of the affection extending from the ligamentous or fibrous structure to the membranes of the spinal chord; and in the gouty form, especially if it be associated with disorders of the secretion or excretion of urine, a favourable result is often long deferred, or even unattainable in very aged persons; whilst in the scrofulous and syphilitic states of the affection, disease of the bodies of the vertebræ, if not constantly, is generally present, and the prognosis is consequently very unfavourable.

78. iv. The CAUSES of spinal irritation have been already noticed (§§ 16. *et seq.*) when treating of the causes of spinal diseases generally; but there are certain causes which are more especially productive of painful or functional disorders of the spine. These are certainly much more frequent in females than in males, the female clothing and physical education of the sex favouring, as shown above (§ 18.), this result. Of 248 cases adduced by Mr. GRIFFIN, 26 only were males. It may occur at any age between 10 and 65; and the gouty and rheumatic forms at much more advanced ages. The nervous variety, the most common in females, is met with from 15 years of age to 65, but most frequently from 20 to 25; in its hysterical form from 15 to 50, the menstrual epoch of female existence. It is much more frequent in the unmarried than in the married, and is not confined to any particular habit of body or temperament; the nervous and lymphatic temperaments, however, predominating. The most common exciting causes are, self-pollution, excessive sexual intercourse, uterine disorder, affections of the

stomach and bowels, the presence of worms in the intestines, or other sources of irritation, as morbid secretions, fæcal accumulations, inordinate exertion, sudden muscular efforts, sprains, exposure to cold and moisture, anæmia, rheumatic fevers or chronic affections, &c.

79. v. The Nature of spinal irritation has been much discussed. The pain in the spine, whether it be constant or remittent, or excited only by pressure of the spinous processes in the seat of the affection, can be viewed merely as a symptom of some lesion, functional or structural, either of the tissues constituting the column, or of the cord, membranes, or nerves, and, in this respect, it is, like the more distant symptoms and sympathies attending it, merely an external expression or manifestation of that lesion, whatever it may be. As no opportunity of examining after death a patient who has been the subject of this affection has occurred, as far as I know, until it has passed into undoubted structural change, and become attended by either inflammatory action, or by paraplegia, it is difficult to infer with any precision what is the nature and exact seat of the affection; but there is every reason to infer, with Ludwick, Hoffmann, and the Franks, that it is connected with, if not the result of, congestion of the spinal circulation. The existence of congestion of the venous sinuses of the spine must necessarily affect the capillary circulation of the cord and its membranes, and the amount of the fluid interposed between them; and, as a consequence of the amount or extent of these changes, the functions of this part of the nervous centres, both sensory and motory, and of the nerves proceeding from it, must thereby be more or less disordered. That inflammatory action, or inflammatory congestion, or indeed any form of chronic inflammation, or its usual results, is not the primary lesion in the purely nervous or hysterical rachialgia, may readily be admitted, when we consider the exhausting nature of its causes, and that exhaustion of organic nervous, or vital power always is productive of congestion in parts on which the causes of the exhaustion more immediately act. But it may be as readily allowed, that chronic inflammation is the more prone to supervene in these parts, the greater or more persistent the congestion, especially if the usual causes of inflammation come into operation. I have seen not a few cases of rachialgia, which had been evidently merely congestive or functional at the commencement, but which, by neglect, or improper treatment, had passed into chronic inflammation of the spinal membranes; and I have even seen some of these, owing to super-added causes, or to perturbating influences, pass into an acute state, the inflammation extending along the membranes, until it reached the base of the brain, and terminated in phrenitic delirium, coma, and death.

80. vi. Treatment.—Rachialgia, according to the local and constitutional symptoms and circumstances of the patient, requires very different, and even opposite, means of cure. The spine ought to be carefully examined, and the habit of body of the patient and the causes of the complaint fully considered, before the intentions of cure are entertained. The particulars to which the attention of the physician should be especially directed are.—1st. The presence or absence of local inflammatory signs, of general vascular disturbance, and of plethora or of anæmia; 2nd. The situation of spinal pain and tenderness, and its relation to existing sympathetic affections; 3rd. The presumed or ascertained causes, and the aggravating circumstances; 4th. The existence or non-existence of interrupted, disordered, or suppressed evacuations, especially the catamenial, and the hæmorrhoidal, where this latter has been often a cause of complaint; 5th. The nature and amount of uterine or sexual disorder with which the spinal affection is allied.

81. *A.* If there be actual evidence of inflammatory action or congestion of any of the spinal structures furnished by the local signs and constitutional symptoms, *local vascular depletions*, according to the severity of these symptoms and the state of vascular fullness, as indicated by the pulse and condition of the veins, are obviously required, the amount of depletion being guided by the indications furnished by these sources. The situation from which the blood should be taken has been the topic of some discussion. J. Frank considers, that local depletion attracts the flow of blood to the seat of depletion; and he therefore recommends the application of leeches to the anus. If rachialgia be connected with scanty, interrupted, or suppressed catamenia, or suppressed hæmorrhoids, leeches may be applied to the anus, or below the groins. In these circumstances, there can be no objection to these situations being adopted: indeed, they are the most likely both to restore the suppressed discharge and to relieve the local affection. But in other cases, there can be but little risk incurred from cupping, or applying leeches on each side of the affected portion of the spine, or even a little above or below this part.

82. *B. Blisters*, and *counter-irritants* of different kinds, have likewise been recommended by several recent writers. J. Frank disapproves of their application over or near the affected part of the spine. I have not seen sufficient cause for not having recourse to them, even in these situations, although they are often employed when they are not obviously required, and where recovery would take place without them. A blister, however, is often very beneficial, and its repetition may be necessary. Mr. Tate, who has very justly insisted upon the connection of this affection with disorders of the uterine functions, prefers the inunction of the spine with the tartar emetic ointment. I have found the liniments or embrocations here prescribed much more certainly beneficial than any other local application, or external irritant; and either may be employed some time after a blister has been applied.

No. 337. ℞ Linimenti terebinthinæ ℥ij; tinct. opii ℥j; olei olivæ ℥ss; olei cajuputi ʒj. ℳ. Fiat linimentum, vel embrocatio ope spongio-pilei applicanda.

No. 338. ℞ Linimenti camphoræ comp. et linimenti terebinthinæ, āā, ℥jss; vini opii ℥j; olei cajuputi ʒjss. ℳ. Fiat embrocatio, vel linimentum.

83. Even when local depletion is required, restoratives, tonics, or antispasmodics may not be the less necessary; but, in all cases, the adoption and the selection of these ought to have especial reference to the ascertained and inferred causes, to the state of the urine, and to the particular character of the sympathetic affections, — neuralgic, hysterical, or spasmodic. If there appear reason to infer, that the affection has been occasioned by masturbation, even local bleeding will generally be injurious, chalybeates or other tonics and re-

storatives being requisite: but, when the complaint has arisen from this vice, or from excessive sexual intercourse, even the best means cannot be of service unless these causes are relinquished. In females, both the spinal affection, and the uterine or hysterical disorder, with which it is generally associated, equally (although either of them may primarily) arise from this vice, and are perpetuated by persistence in it: and hence the use of the speculum uteri, and of other phalloid instruments, is so gratifying to the patient. In all cases, the urine should be carefully tested, and the treatment regulated conformably with the states presented by it, as fully described in the article on the Urine, and on the disorders connected with this excretion.

84. *C.* When spinal irritation is associated with suppression of the catamenia, then the application of leeches below both groins, two or three days previously to the expected period, and the exhibition of equal quantities of the aloes and myrrh pill, and of the biborate of soda, or of the compound iron mixture and compound decoction of aloes, in doses sufficient to act freely on the bowels, will frequently be efficacious; more especially if the embrocations prescribed above, or No. 311. in the Appendix, be applied to the spine, and repeated according to its effects. In many of these cases, not only are the catamenia irregular, sometimes excessive, but more frequently defective, scanty, suppressed, or difficult and painful; a more or less profuse or continued leucorrhœa often replacing the healthy periodic discharge. In some, these complaints are further complicated with anæmia or chlorosis, and ultimately terminate in irremediable visceral disease. The treatment of these complications, even in their milder forms, is always difficult, and in their severe forms often hopeless, especially when the vice in which they originate is persisted in. The spinal and the sexual disorder frequently act and re-act on each other, until ultimately paraplegia and various associated evils are produced. The uterine affection suggests either vaginal injections or an examination per vaginam; the speculum follows, and various applications are made to the os uteri, of a stimulating, astringent, or irritating nature. As the os uteri possesses an organic sensibility, but little, if at all, inferior to that manifested by the clitoris in the sexual orgasm, neither the vaginal injections, nor the phalloid instrument, nor the applications made by its aid, are at all unpleasant to the self-polluted female. The local irritation thus produced, increases or at the least perpetuates, by nervous communication, the spinal affection; and after the constant attendance of "ladies' doctors" for many months, or even years, the patient having become paraplegic or generally paralysed, and having continued in this state for months, requiring the urine to be drawn off twice or thrice daily, besides other aids, ultimately dies from the extension of disease to the cerebral membranes, or from organic changes in the spinal cord, or in its membranes, or in the kidneys, or in some other organ.

85. As the patient sows, in such cases, so she reaps. But let not the treatment be a perpetuation of the cause of the malady, in a different form—let not the physician furnish, not merely a novel mode, but even a new instrument, of self-pollution; and thus minister to the accursed moral taint of his patient. In many cases, doubtless, this is done unknowingly, by his adopting a method brought into vogue by others and pleasing to the patient, and by his ignorance of this cause of these complaints, — a cause which obtains in at least nine cases out of ten. In most of these the patient will confess to the vice, which has occasioned the disease, if the matter be judiciously managed; and even if this vice should not be admitted, a full exposition of the consequences of persisting in it will produce a good effect; for many patients sin from ignorance, and are not conscious of the evil they are committing. I have had many instances illustrating this position, brought before me. Others (but these are comparatively few) persist in this cause, and either require some restraint or go on, until a drivelling amentia, or irremediable structural disease, overtakes them. When there is reason even for suspecting the existence of this vice, the physician does not discharge his duty to his patient, and to the family of the patient, if he does not investigate the case as circumstances will suggest or admit of; for, if this cause be continued, a cure will be impossible, but by relinquishing it, remedies will be successful, and even the efforts of nature will of themselves be often efficacious. There is one circumstance, which may not be known to many of those who are so much in the habit of recommending stimulating and astringent injections, and irritating or escharotic, substances, to the os uteri, by the aid of large glass or other syringes, or of specula—namely, that similar, and even many of the same, substances were thus employed by the ancients, and by the Chinese and Tartars from remote ages, to excite or to gratify the sexual desires; and that the modern treatment, by these means, of uterine disorders, whether allied or not to spinal irritation, can neither permanently cure these complaints, nor remove "a rooted evil" from the mind.

86. *D.* When the spinal affection is associated with neuralgia, then the preparations of iron, or the sulphate of iron and sulphate of quina, with camphor, hyoscyamus, and as much of the aloes and myrrh pill as will keep the bowels freely open, will be of service, the embrocations prescribed above being applied to the pained portion of the spine; or the treatment advised for Neuralgic Affections may be adopted. If the spinal disorder have been induced by masturbation, or if it be connected with suppressed or scanty catamenia, the combination of substances just now recommended will be of service. If, on the other hand, it be associated with leucorrhœa, or with a superabundance of phosphates in the urine, or with involuntary pollutions, the tincture of the sesquichloride of iron, with a small addition of hydrochloric acid, may be prescribed, with the infusion and tincture of either columba or quassia. In most cases of spinal irritation, the treatment should depend, in great measure, upon the character of the associated or sympathetic affections — whether neuralgic, spasmodic, or hysterical; due attention being also paid to the digestive, assimilating, excreting and uterine functions. But unless the causes be recognised and avoided — unless correct hygeienic measures be also adopted, based upon the predisposing and exciting causes above insisted upon (§§ 16, 78.), the treatment will very frequently be inefficacious.

87. In some prolonged cases of spinal irritation

or congestion, associated with uterine disorder, complete paralysis of the bladder, irritability of the stomach, constipated bowels, and paraplegia, especially as respects the function of motion, sometimes occur. This severe form of the disease generally results from self-pollution, and often resists almost every kind of treatment, if this vice be not discontinued. I have seen several cases of this kind, and the means which I have found most efficacious are, the assiduous application of one or other of the embrocations or liniments already recommended, along the spine; and the use of the iron or myrrh mixture, conjoined with the decoction of aloes, or the pills prescribed above (§§ 53, 84.). Various other means have been also employed, according to the features of particular cases—as the iodide of iron in syrup of sarza, or the iodide of potash in tonic infusions, and occasionally the resinous extract of nux vomica, conjoined with the aloes and myrrh pill. In a severe case of this kind, attended by vomitings, retention of urine, suppression of the catamenia, &c. which I saw with Mr. FLOCKTON, a large pea-issue was made in the inside of both thighs, close to the groins, and a free discharge procured. The paraplegic and other symptoms soon disappeared, and the patient was quite recovered in the course of a very few months.

88. When spinal irritation or congestion has become chronic, it is sometimes accompanied with attacks of faintness, or leipothymia, and, in rare cases, with cataleptic seizures — with the latter, chiefly when the affection has been produced by manustupration. In these, the treatment already advised, or that prescribed in the articles on these affections, will be appropriate. These disorders are chiefly aggravated forms of hysteria, and are to be treated conformably with the principles insisted on, under the heads of DEBILITY, FAINTNESS, HYSTERIA, NEURALGIC AFFECTIONS, and SPASM: and for these, as well as for spinal irritation and spinal curvature, a digestible and moderate diet, at regular, but not too long intervals between the meals, gentle exercise in the open air, change of air, of scene, and of locality, a residence in a dry and temperate situation, the use of chalybeate mineral springs, or of such mineral waters as the state of the catamenia or of the urine in individual cases will suggest, are important remedies, —indeed, the most requisite elements of the treatment of this group of disorders.

89. *E.* When rachialgia is connected with *rheumatism*, or with *gout*, or with *scrofula* or *syphilis*, the local means already advised may be employed, according to the features of the case; but the treatment should be in great measure based on the constitutional complaint of which the rachialgia is merely a manifestation. In some cases, particularly the rheumatic, gouty, or scrofulous, leeches may be applied, and even repeated, to or near the affected portion of spine, and be followed, by blisters, or by the terebinthinate embrocations and a constitutional or internal treatment suited to the peculiarities of the case, especially by the iodides in the preparations of sarza, the iodide of potassium with the solution or carbonate of potash, and tonic infusions or decoctions; or the bi-chloride of mercury, taken with a full meal, or in a tonic infusion; or DONOVAN's solution of the iodide of mercury and arsenic, and the preparations of sulphur subsequently, or the sulphuretted mineral waters. In these forms of the complaint, as well as in the nervous or hysterical, avoidance of the causes, a due promotion and regulation of the digestive and depurative functions, and strict attention to diet, regimen, exercise, air, locality, and the purity of the water in use, are essential parts of the treatment.

90. V. CONCUSSION OF THE SPINAL CORD.— The nature and extent of injury sustained by the spinal marrow in circumstances of violence which occasion concussion of this part of the nervous system, can rarely be ascertained soon after its occurrence, and sometimes not even after death.— *A.* The *causes* of concussion are generally falls from a height on the back or trunk, or upon the hips, upon the ground, or even upon any partially yielding surface that may not occasion fracture or dislocation. A violent blow on the back, jumping from a height, a railway concussion or shock, or any sudden or violent succussion of the trunk also may occasion it, in a slight or in a severe form, according to the circumstances of the case.

91. *B.* The *symptoms* vary with the violence and nature of the cause, but consist chiefly of an impairment, in slight cases, and of a more or less complete extinction in severe cases, for a longer or shorter period, of the functions performed by the spinal cord. There are loss of voluntary motion and of sensation, either or both of which may be partial or complete, especially of motion; the excreting functions being generally more or less affected, and the functions of respiration and circulation much disturbed. In most cases, particularly when the concussion has been violent, diminution of temperature, failure of the pulse, pallor, and the other phenomena characteristic of *physical shock* (see art. SHOCK), are also present.

92. *C.* The *appearances after death* are frequently so slight, or even when most manifest, are altogether such as are insufficient to account for the effects in rapidly fatal cases; and, in those of longer duration, they are generally consecutive upon the change more immediately produced by the concussion. It may be presumed that, in those cases of severe concussion, which are soon followed by dissolution, and yet present no appearance of lesion, the intimate organisation of the cord has sustained an injury incompatible with the discharge of its functions and the continuance of life, although the injury may escape the detection of our senses. In cases of longer duration, softening of the cord, with or without inflammatory appearance, either in the cord or in the pia mater, is often observed; but frequently the softening follows rapidly upon the concussion before inflammatory action supervenes, or even before it has had time to appear.

93. *D.* The *treatment* of concussion of the spinal cord differs not in any respect from what I have recommended when treating of SHOCK (§§ 19. *et seq.*).

94. VI. SPINAL COLUMN. — INFLAMMATION AND CARIES OF THE VERTEBRÆ. — SYNON:— *Inflammation of the vertebræ, and of the intervertebral substances:—Mal vertebral, Fr.— Pott's disease of the spine:—Spinitis; — Inflammation and caries of the spine.*

CLASSIF.—III. CLASS.—I. ORDER (*Author.*)

95. DEFINIT:—*A dull and generally a continued pain in some part of the spine, with slight fever, manifested chiefly towards evening, and often attended by a sense of constriction around the trunk in a*

situation corresponding with the affected portion of the spine, terminating generally in caries, or in symptomatic abscess, or in both.

96. i. Description.—The structures constituting the spinal column are liable to inflammatory action, from sprains, injuries, external violence, from cold, and from constitutional vice or a morbid diathesis. The inflammation thus produced may advance silently and slowly for a considerable time, and suddenly assume a more active or acute form: the affection may even be sub-inflammatory at first, and escape detection, or it may be more acutely inflammatory, and more manifestly declare itself, but it is commonly chronic or slow in its progress. When the disease appears in the scrofulous diathesis, as it does in the majority of instances, it then consists of tuberculous deposits in the cancellated structure of the vertebræ, and can hardly be viewed as inflammatory at the beginning, although it becomes so, in some measure, owing to the irritation caused by the morbid deposit. When it thus proceeds from tubercular deposits, the cancellated bodies of the vertebræ are generally their seat. But it may appear, especially in weak or cachectic constitutions, independently of tubercles, although this occurrence is comparatively rare, and commence either in the intervertebral substance, or in the bodies of the vertebræ, or even in the ligaments covering the spinal column; and ultimately involve the other structures. A recent writer justly remarks, that "the vertebræ in their natural structure are extremely cancellated, and of a vascular texture; and any increase in the circulation of this part may induce inflammation. The ligaments covering the spinal column are also extremely vascular, and the vessels supplying both freely communicate; so that when any increased vascular action is set up in the structure of either, it may continue for some length of time, and very considerably in its activity, relatively to its cause. We observe an example of this in cases where the ligaments are strained by some sudden or powerful exertion. This brings on inflammatory action, in which the cancellated structure of the bones participates, owing to the free communication of the vessels of these two parts." E. W. Tuson, *on Curvatures of the Spine*, &c. p. 218. 8vo. London, 1841.

97. *A.* Inflammation having commenced, it may continue a long time without giving rise to any severe symptom, until at last the motions of the spine, by perpetuating and aggravating the inflammation of the fibrous membrane covering the bones, cause thickening or swelling of it, which, with the products of the inflammation thrown out within the spinal canal, occasions pressure or irritation of the cord, or of the roots of the nerves, and the various spasmodic and paralytic symptoms, which sooner or later supervene. Whether the disease commences in this more unequivocally inflammatory form, or in that of tubercular infiltration of the cancellated structure, on which the inflammation is contingent, the progress it makes is slow, and its nature frequently not clearly declared. There is generally pain in the portion of the spine affected; but this is the case in rachialgia; so that it is difficult, and often impossible, at an early stage to distinguish between this complaint and that, until the inflammation has induced dangerous changes (*see the Diagnosis*).

98. When the disease of the cancellated structure is produced by tubercular infiltration, as it is most frequently, the spinal cord and its membranes are then very rarely implicated until caries has occurred, this lesion often then irritating and affecting the ligaments and membranes, and producing the same symptoms, especially spasms, cramps, paralysis, &c., as generally, at a much earlier period, accompany chronic inflammation of the ligaments covering the bodies of the vertebræ, or of the intervertebral substances. In whichever tissue the inflammation may commence, or whether it originates in this state of morbid action, or in tubercular deposits in the cancellated structure, softening of the bodies of the vertebræ generally results, and the softened structures yield to the weight of the superincumbent parts of the body, and ultimately caries take place. Pott, who was the first to describe accurately this affection, viewed it as generally scrofulous. Paletta, however, contended that this is not the case, and that it often arises independently of the scrofulous taint. In this view Pott has been supported by Boyer, Dugès, and others. Nevertheless, Paletta is in the main correct, for it sometimes proceeds from the following causes, independently of scrofula, although these causes will very readily induce it in the scrofulous diathesis also.

99. *B.* The *Predisposing* occasions of the malady are not infrequently severe attacks of exanthematous fevers, unwholesome or insufficient food, and a humid or impure air in childhood; masturbation about the period of puberty; a syphilitic taint, or general cachexia, and the excessive use of calomel, or of other mercurials in childhood or infancy. The most common *exciting* causes of the inflammatory states of the affection are exposures to cold, external injuries,—as falls, blows, sprains, severe jerks, or sudden twists, or forcible rotations of the spine, and over exertion of the muscles, especially in endeavouring to lift very heavy bodies. A blow over the lower dorsal or upper lumbar vertebræ, particularly when a child or young person is struck in this situation, is very remarkably injurious; for the weight of the upper part of the body carries this part backwards with a sudden jerk or impetus, whilst the parts struck are as forcibly driven forwards. The results are, if the blow be severe, either a luxation or subluxation of two or more of the vertebræ, or a rupture of, or severe injury to, the ligaments and intervertebral substance. The more manifest effects of injuries of this nature may not become manifest until some months have elapsed from their receipt. In such cases, inflammatory action of a slow or chronic kind is occasioned; and this is followed either by thickening, swelling, effusion, or purulent infiltration between the membranous ligaments and the bone, and, as a consequence of the latter changes, by caries of the bodies of one or more vertebræ, or by infiltration of puriform matter between the ligaments and muscles, thereby causing symptomatic abscesses. Disease of the bodies of the vertebræ, proceeding on to caries, consists—1st, of inflammation of the cancellated structure—of an *osteitis vertebralis* of some writers, the *ostéite raréfiante* of M. Gerdy; and 2dly, of tubercular deposits in this structure.

100. *C.* Inflammation commences with increased vascularity of the surface of the affected vertebra,

followed by erosion or incipient ulceration. At a more advanced period, the body of the vertebra is swollen, injected, and of a deeper red colour. At the same time its structure is less dense, softer, and more friable; and is hence more disposed to yield, or to be compressed, or injured by the weight of the superincumbent parts, or by suddenly bending or rotating the trunk, or when lifting heavy bodies. This form of the disease may also commence in the ligaments covering the bodies of the vertebræ; and it may be connected with acute or sub-acute rheumatism, especially when commencing in the ligaments, although this is a rare occurrence: but, however occurring or associated, it may extend to the periosteum, the inflammatory products infiltrating the adjoining parts, detaching the periosteum from the bone, and thereby causing caries of the latter; or it may even originate in the intervertebral fibro-cartilaginous substance, and extend to the other structures, more especially to the bodies of the vertebræ.

101. The disease may commence in the centre or in the sides of the bodies of the vertebræ. In this case, the bone is found to have become redder, softer, and more vascular, and less capable of sustaining a super-incumbent weight or pressure; and the progress of the disease is generally more rapid than when it begins in the intervertebral cartilage, or in the ligaments. If the disease commences in the membrane covering the upper and lower portions of the bodies of the vertebræ, the attachments between these become weakened and ultimately destroyed, and the malady proceeds with considerable rapidity. When it originates in the centre or in one side, or anterior part of the intervertebral substance, ulceration frequently follows, or suppuration supervenes from the extension of the inflammation, the matter infiltrating the adjoining tissues, and either causing or extending the caries of the bone. When the disease commences in the centre of the intervertebral structure, a softened, greyish, and brownish state of the structure is observed; and this is followed by ulceration, disease of the bodies of the vertebræ, caries, suppuration, &c. In these cases, the disease of the structure may advance anteriorly, or to either side, and, according to its direction, occasion not only a more or less angular form of curvature, but a lateral curvature also; a circumstance requiring attention in forming our diagnosis and prognosis. Thus disease of the bodies of the vertebræ may be either primary, or the consequence of inflammation, suppuration, and ulceration of the intervertebral substance, and of the ligamentous apparatus of the column.

102. *D.* Tubercular disease of the bodies of the vertebræ occurs either as an infiltration of the cancellated structure with tubercular matter, or as an agglomeration of the matter into masses, which are surrounded by a cyst or envelope; this latter being more frequent and most manifest. In these cases the tubercular masses undergo similar changes to those observed in the lungs; and as they pass from a crude to a softened state, excavation and ulceration of the containing or surrounding parts takes place, until the vertebra is nearly reduced to a shell, or is formed into several cells, and becomes crushed under the superincumbent weight; the spinous processes of the diseased vertebræ, which at first were merely tender and prominent, rapidly becoming angular, and passing from an obtuse to a more acute form. As soon as the curvature presents a sharp or angular projection, destruction or loss of substance of a part of one or more of the bodies of the vertebræ may be inferred. The resulting deformity will depend upon the portion of the spine affected, and the extent of destruction which has taken place.

103. ii. The Symptoms and Diagnosis of this state of spinal disease are extremely delusive at an early stage, and before curvature becomes manifest; and it is still more difficult to determine, even at any stage of the complaint, in many cases, whether the malady results from inflammatory action, or from tubercular deposition, or from both, either having been the primary change. A knowledge of the constitution or diathesis of the patient, of the causes which have produced the disease, and of the whole history of the case, will often throw considerable, or even sufficient, light on its nature; but these data may be wanting, and the only information which can be obtained may be afforded only by the existing state of the patient, or even by the angular distortion demonstrating more or less destruction of the bodies of the vertebræ. Whilst the scrofulous diathesis, and the stealthy progress of the affection, indicate tubercular deposits as the cause in the one case, the previous occurrence of injury, and the absence of the scrofulous taint, will suggest inflammatory action in the other; and, when viewed in connection with more or less pain, and with the other symptoms, will often evince the nature of the mischief, even before it has advanced to angular projection. Pain is not, however, a constant symptom even in the more inflammatory state of the disease, especially at an early stage, and often it never amounts to more than an aching; whilst in the scrofulous form, pain may not be much complained of, unless on some occasions. As the disease advances, pain is either more constant, or more severe, especially in certain postures, or when rotating or bending the spine; and it is attended by a sense of constriction and pain in the base of the thorax and epigastrium, or in the abdomen, according to the part of the spine affected. Even before any marked curvature is detected, this constrictive pain is often felt, and the patient sometimes complains of a grating sensation when turning or rotating the spine, more especially when the disease originates in inflammation of the vertebræ, or of the spinal ligaments. In addition to these symptoms, nausea, vomiting, attacks of pain at the epigastrium, dyspnœa, restlessness, costiveness, and evening exacerbations of fever supervene, with increased sensibility of the surface, and cramps, or sometimes numbness of the lower extremities. These may continue an indefinite, but generally a considerable period; the angular character of the curvature becoming more and more manifest. The patient now is generally unable to sustain the weight of the parts above the diseased portion of the spinal column; and he endeavours, when erect, to support himself by leaning upon his elbows or arms, or by placing his hands upon his hips or thighs. He becomes also less capable of walking, his gait being unsteady, shuffling, or peculiar and slow.

104. Whether originating in inflammation, or in tubercular deposits in the bodies of the vertebræ, the angular projection of the spinous processes is not very great until caries of the bone, and ulcer-

ative destruction of the intervertebral substance, have advanced. The loss of structure in a portion of the column, owing to the weight of the superincumbent parts, is attended by more or less distortion, not only of the posterior aspect of the spine, but also of the anterior regions of the trunk. According as the cervical, the dorsal, or the lumbar vertebræ are diseased, the distortion varies remarkably, and as a necessary consequence of the difference in the conformation and attachments of the vertebræ of these regions.

105. *a*. When the *cervical vertebræ* become carious — an occurrence, according to my experience, observed chiefly as a sequela of scarlet fever—the curvature or projection of the spine is not marked; but the neck becomes shortened, drawn somewhat to one side, and is moved with great pain. Partial or incomplete paralysis, chiefly of motion, is often experienced, and frequently increases or passes into general palsy, terminating in asphyxia. Yet I have seen cases in which anchylosis took place, the recovery being complete and permanent, the neck being only shortened, and rendered stiff, the head being generally turned somewhat to one side.

106. *b*. When the *lower cervical* and *upper dorsal vertebræ* sink from loss of structure, the chest is flattened, the sternum is drawn inwards and downwards, and the patient generally experiences difficulty of breathing, owing to the impaired action of the scaleni and other respiratory muscles. The depression of the chest anteriorly is often very great in these cases. When the middle or lower dorsal vertebræ are diseased, the chest is either flattened anteriorly, or in a lateral direction, one side falling inwards more than another; or either side may be compressed whilst the other projects; or both sides may be flattened, and the sternum pushed forwards. The thorax always approaches very close to the pelvis, and the abdomen is much shortened. The distortion varies much with the seat and extent of caries; and, according as either side of the vertebræ is more affected than the other; the posture most commonly assumed by the patient, and found most easy, also influencing the form of distortion.

107. *c*. When the *lumbar vertebræ* are diseased, the lower or floating ribs are sunk inwards and downwards, and sometimes even below the crests of the ilium. The abdominal regions fall inwards, and are much diminished in their vertical direction. Owing to a greater or less amount of caries in one side of the vertebræ than in the other, or to continuing a certain posture in preference to any other, or to spasm, or permanent contraction of certain muscles, more or less of lateral curvature may be associated with angular projection of the spine, the caries being the cause of both the forms of curvature. When these cases terminate favourably, or when anchylosis takes place, this associated form of curvature may exist to a greater or less extent, and even be attended by some degree of twist, or contraction of the trunk to either side.

108. iii. The Consequences, Complications, and Terminations of angular projection or curvature of the spine are—1st, changes in the tissues external to the spinal column, or in its vicinity; 2nd, changes in the structures lodged in the spinal canal, and in the nerves issuing from the canal; and, 3rd, alterations of a restorative nature in the seat of the disease.

109. (*a*.) When inflammation, ulceration, or caries exists in one or more of the vertebræ, the usual products of these changes frequently contaminate the adjoining cellular tissue, induce inflammatory action, and give rise to purulent formations, which pass in various directions, according to the peculiarities of the case, ultimately pointing externally, or even internally, at a distance from the original seat of disease, as fully shown when treating of *symptomatic abscess*. (See art. Abscess, §§ 24. *et seq.*)

110. (*b*.) Although inflammation or caries of one or more of the vertebræ often exists without implicating the spinal cord, or its membranes, or even the nerves proceeding from the canal, nevertheless the membranes are often affected, a chronic form of inflammation being developed, which may be followed by effusion of lymph, and by consecutive changes in the cord, or in the roots of the spinal nerves. When the membranes or cord are thus implicated, the symptoms about to be described, as indicative of inflammation of these parts (§§ 120. *et seq.*), are observed, and are usually followed by incomplete or complete paraplegia, and often by the extension of the morbid action along the spinal membranes to the base of the brain, occasioning general paralysis, delirium, coma, and death. But, independently of any affection of the cord, or of its membranes, the nerves may be subjected to pressure, owing to the attendant swelling of the parts surrounding their exits from the spine, or to the destruction of parts in the progress of caries. If the pressure be slight, or if it occasion merely irritation of the nerves, severe or neuralgic pains in the course or terminations of the affected nerves, or cramps of the muscles supplied with them, will be experienced; but if the pressure be greater, paralysis of motion, or of sensation, or of both, will be present. Thus, owing to consecutive affection—to the consequent congestion, irritation, or inflammatory action, tumefaction, effusion, and pressure, implicating the membranes of the spinal cord, the origins of the spinal nerves, and even the cord itself, pain, spasm, paralysis, &c. supervene and complicate the disease of the vertebræ; and, with or without either of these states of associated disorder, suppuration not infrequently takes place in the adjoining cellular parts, and purulent collections form, and often extend to considerable distances from the seat of caries (§ 109.). In most cases, pain of a severe form is experienced in the seat of lesion, and even still more severely in the lower extremities, whilst the urinary functions are often more or less disordered.

111. (*c*.) When the destruction of one or more of the vertebræ has proceeded to an indefinite extent, a reparative process—*anchylosis*—often commences, owing to a salutary change in the constitution of the patient, produced either by an improvement in the diet, or in the air, or by a judicious treatment; and a matter is exuded, which becomes the seat of an osseous formation, cementing the adjoining vertebræ, and often partially filling up the spaces left by the destruction of the bodies of one or more of the diseased vertebræ. In these cases, the intervertebral and cartilaginous portions of the spine which have been destroyed are not restored, the osseous formations extending, without loss of continuity, but with varying grades of thickness, from the adjoining healthy vertebræ.

112. iv. THE DURATION AND PROGNOSIS of caries of the vertebræ may be inferred from what has been already advanced. The *duration* of the malady is rarely less than two or three months, and it may be as many years. The *prognosis* depends much upon the habit of body, and previous health of the patient. Also upon the presence of suppuration, or of paralysis, or of both. Matter often forms and collects near the column, especially its anterior surface; and, in the more favourable of these cases, opens externally, the track of the matter being sometimes very long, and the external opening distant from the diseased vertebræ. The carious destruction may, even in some of these cases, be repaired by anchylosis, and by the column falling together at the angle corresponding to the quantity of substance lost; but much more frequently the disease exhausts the patient, the symptoms usually showing that the spinal cord and its membranes suffer more or less. Thus the cord itself may be compressed by tumefaction of the ligamentous apparatus, by the irruption of an abscess into the canal, by dislocation of fragments, or of the whole, of a vertebra, or by the products of circumscribed inflammation of the dura mater of the cord; or it may be bent, pressed upon, or irritated, at the spot where the angular projection is commencing; or it may waste, or circumscribed inflammation may take place in it, or diffused inflammation in its membranes. When the upper dorsal vertebræ are carious, the abscess sometimes opens into the thoracic cavity, or into one of the bronchi, and matter and necrosed or carious fragments of vertebræ are discharged through the air-passages. Caries of the abdominal part of the column is very often complicated with what is commonly called *psoas abscess*.

113. The prognosis may be further directed by the following symptoms:—If a scrofulous or syphilitic taint exist; if the constitutional or vital powers be much depressed; if symptoms of inflammation of the membrane appear; if palsy, or even cramps, supervene; and, more especially, if the palsy extends; if febrile symptoms with delirium are present; and if the urinary functions are much disordered, an unfavourable opinion of the issue should be entertained. On the other hand, if the general health be not greatly impaired; if the several excreting functions are not materially affected; if sensation and motion are not disordered; if pain or constriction is not present, and if the digestive and assimilative functions are not much disturbed, more or less complete restoration to a healthy state, by means of anchylosis, may be expected.

114. v. TREATMENT. — The means of cure should depend chiefly upon the causes and circumstances originating the disease. If inflammatory symptoms be present at an early stage,—if these have followed a blow, sudden jerk, or injury of any kind; and if constriction, severe pain, increased by motion, be complained of, the application of leeches, or of cupping glasses, near the seat of pain, will generally be serviceable. These may be followed by a terebinthinate embrocation, or by a blister, the latter being applied considerably below the seat of the disease; or the blister may follow several applications of the embrocation; or it may be kept discharging for some time. These means, however, ought to be employed, or persisted in with due caution, and a careful observation of their effects.

115. If the disease appear independently of any injury, violent exertion, or inflammatory cause; if it come on in a gradual or stealthy manner; if it occur in a scrofulous, cachectic, or syphilitic diathesis, or taint; if the patient feels a grating sensation when rotating the trunk; and if indications of purulent formations in the vicinity, or of a symptomatic abscess, are present, neither leeches, nor cupping, nor blisters, will be of any service; they will much more frequently be prejudicial. In these forms and states of the disease, such means as will remove the weight of the upper parts of the frame from the diseased vertebræ, and promote vital resistance to the extension of the disease, and improve the digestive, assimilative, and excreting functions, have been found most beneficial in my practice—even in some cases of great and almost hopeless severity. A combination of these, with such as more frequently produce an alterative influence upon the capillary circulation, more especially with the preparations of iodine, or with the bichloride of mercury, or with the solution of potash, or Brandish's alkaline solution, ought always to be preferred. I have often found that a change from a course of some continuance of the one, to that of another form of combination, has been of manifest benefit—that the exhibition of the bichloride, in the simple or compound tincture of cinchona and fluid extract, or concentrated compound decoction of sarza, for a longer or shorter period, according to circumstances, followed by the compound tincture of iodine, or the iodide of potassium, with BRANDISH's solution, or the carbonate of potash, and the other preparations just mentioned, has been of very essential benefit.

116. When the inflammatory form of the disease has gone on to the production of caries, or to suppuration, and in the scrofulous, syphilitic, or rheumatic states, the above means are most deserving adoption, and may often be aided by the application of the liniment already prescribed (§§ 54.) along the spine, or of some one of the other terebinthinate liniments prescribed in various parts of this work, as well as in the *Appendix*. When the disease is attended by anæmia and much debility, then the preparations of iron, especially the iodide of iron, should be given in syrup or sarza, or in other suitable forms. In the several scrofulous states of the disease, the means advised for the treatment of SCROFULA (§§ 172. *et seq.*) will be of more or less service. The propriety of having recourse to issues, or setons, or moxas, or other forms of derivation, has been a subject of discussion. POTT recommended issues on each side of the projecting spinous processes, and the practice has been very generally adopted since his time, with apparent benefit in some cases, and with no advantage in others. Sir B. BRODIE, an authority of the greatest weight, states that he has seen no benefit result from the use either of these or of blisters. There can be no doubt that they are not so generally, or even so often, beneficial, as they were formerly believed to be, and that an indiscriminating recourse to them is as frequently injurious as beneficial; but, if due regard be paid to the form, state, or progress of the disease, they will often be of service; if, however, caries be extensive; if it be attended

by anæmia, great emaciation and debility; if the digestive, assimilating, and excreting functions be much impaired; and if the medicinal and regimenal treatment be not prescribed appropriately to the state and peculiarities of each case, these and similar means will not only entirely fail, but will even accelerate a fatal issue, by lowering still further the already depressed condition of vital power, and by increasing the extent of caries, or the amount of suppuration, or of vascular contamination. I have usually had recourse to these means only after inflammatory symptoms have been combatted as far as circumstances permitted, and when the contra-indications to their use were not present; and during their employment I have advised the tonic and alterative treatment already mentioned (§§ 115, 116.), with due attention to diet, change of air, &c.

117. Whilst duly regulated modes of *exercise* are beneficial in other kinds of curvature, perfect *rest* is requisite in this; but rest should be aided by a wholesome air, and a well-ventilated apartment. The use of those couches which facilitate the *prone* posture should be adopted; and, whilst all measures which forcibly extend the spine and risk injury to the structures contained by or adjoining the diseased vertebræ, ought to be avoided, the position chiefly maintained should as much as possible be such as will prevent the increase of curvature. This is as much as may be expected from couches merely; but, either with or without these, the avoidance of all motions of the vertebræ—either of flexure or rotation—ought to be studied. Forcible extension of the flexed portion, or forcible depression of the projection, may injure the early reparative changes of the diseased parts, by which anchylosis, and a restoration to a comparatively healthy state are affected.*

118. The consecutive disorders (§§108-111.), especially symptomatic abscess and paralysis, which often complicate angular curvature or caries of the spine, caused either by inflammation or scrofulous disease of the vertebræ, should be treated conformably with the views above exhibited, but appropriately to the stages and states of each case, and to the particular disorders which have been thus superinduced. As to the additional means which these latter require, I must refer the reader to what has been fully stated respecting them when treating of *symptomatic abscess.* (See ABSCESS, §§ 62. *et seq.*), of *Paralysis* (§§ 204. *et seq.*), and of *Spasm* (§ 313.), where such measures as are most suitable to each of these associations are described.

119. VII. INFLAMMATION OF THE MEMBRANES, AND OF THE SPINAL CORD.—SYNON.—*Rachialgitis*, J. Frank:—*Rachialgia Inflammatoria—inflammation commencing in, or extending to, either the spinal cord or its membranes, or both.*

CLASSIF.—III. CLASS.—I. ORDER (*Author*).

120. DEFINIT.—i. *Pain in the spine, often acute, with or without rigors, commencing with increased sensibility of the surface of the body, and symptomatic fever, followed by spasms, cramps, constriction, &c., especially on motion, passing into palsy, usually in the form of partial or complete paraplegia, or general paralysis, with interrupted or disordered excretion.*

121. ii. PATHOL. DEFINIT.—*Inflammation occurring primarily in, or extended to, either the dura mater, or arachnoid, or pia mater of the cord, or the spinal cord itself, and generally implicating two or more of these, followed by thickening, effusions, adhesions, disorganization, &c.*

122. The diseases of the spinal cord, whether inflammatory or structural, present numerous analogies to those of the brain, not merely in their natures, which are frequently identical, but also in the phenomena to which they give origin. My friend Dr. WOOD, of Philadelphia, justly remarks in his very excellent work, that there is in both brain and spinal marrow the same liability to inflammation of the membranes and the nervous matter, to derangement from non-inflammatory organic affections, including hæmorrhagic and serous effusion; and these different affections in the one not infrequently merely extensions of the same affections in the other. Like the brain, too, the spinal marrow contains nervous centres and conducting filaments, and it may suffer disease in these constituents separately or conjointly.

123. The spinal cord discharges certain offices, a knowledge of which is necessary to the diagnosis of its diseases.—1st. It receives impressions from other parts of the body, and transmits influence to these parts, either independently of the brain, or with the due exercise of the functions of the brain;—2nd. It conveys influence to and from the brain;—3rd. It is the medium by which impressions or influences are often conveyed from the ganglial centres to external and voluntary parts, and from the latter to the former.—(*a.*) According to its *first* office, it aids the ganglia in the discharge of their functions, and reinforces their energies; whilst, on the other hand, the ganglial influence is extended to it, by means of communicating or anastomosing branches. Hence lesions of the cord or of its membranes very manifestly affect respiration, assimilation, secretion, excretion, and reproduction.—(*b.*) Conformably with its *second* office, voluntary motion or sensation, or both, are interrupted, or disordered, or perverted, when either the spinal marrow or its membranes are diseased.—(*c.*) And, according to its *third* office, irritation or other affections of internal viscera, digestive, excreting, and reproductive, are frequently transmitted to external, distant, and voluntary parts, and from these latter to the former, as illustrated by the origins and courses of many diseases.

124. It is manifest that the amount, as well as the character and seat of disorder, will vary remarkably with the particular structure inflamed, or otherwise diseased, and with the situation of the diseased part in the spinal canal, or with the extent of it along the cord. In estimating, therefore, the seat and nature of the malady indicated by the symptoms, certain pathological conditions should be kept in recollection:—1st. Disease or injury of the vertebræ, or of the intervertebral substance, or of the ligamentous apparatus, may, by irritation or pressure, more or less interrupt, disorder, or pervert the functions discharged by the spinal cord. 2nd. The products of congestion, or of inflammation of the membranes, may, by irritation or pressure, exert a similar influence, in respect of the offices of the cord, independently of any actual or manifest disease or change

---

* I have great pleasure in referring the reader to what Mr. BISHOP has stated on this subject, in his very able and philosophical work on Deformities of the Human Body, which appeared as this sheet was passing the press.

in it. 3rd. That inflammation, aided by its usual products may, on the one hand, extend not only to two, or to all the membranes, but also to the substance of the cord itself. 4th. That inflammatory or other lesions of the cord itself, may, on the other hand, extend to one or all its membranes. 5th. That this extension of the disease to the several structures is more frequent than the limitation of it to one only; and the extension of morbid action, more or less along the spinal membranes and cord — or even to the base of the brain—is much more common, especially in very young subjects, than the limitation of it to a part only. 6th. That the extension and diffusion of inflammation is more rapid and general in the membranes than in the substance of the cord; and more so in delicate, scrofulous, and cachectic habits, than in the robust and healthy. 7th. That, as far as my own experience enables me to judge, the extension of meningitis spinalis upwards to the brain is much more frequent than the extension of it downwards along the spine; and the latter mode of extension, as well as the complication of spinal meningitis with cerebral meningitis, is most frequent in very young and delicate children, and in cachectic and broken down constitutions.

125. Although inflammation of the membranes is often associated with inflammation of the substance of the spinal cord, the disease commencing or predominating in either, still the one or the other may be separately, solely, or chiefly inflamed; and hence it is in some measure requisite to consider the phenomena which more especially belong to each, and which indicate a more prominent affection of one structure than of the other, when they are all more or less implicated. I shall therefore first notice inflammations of the membranes, and next inflammation of the substance of the cord.

126. i. INFLAMMATION OF THE MEMBRANES OF THE SPINAL CORD. — SYNON. — *Meningitis spinalis — Arachnitis spinalis — Meningite spinale,* Fr.—*Spinal Meningitis.*

127. DEFINIT.—*Acute pain in the course of the spine, with or without rigors, attended by increased sensibility of the surface of the body, by symptomatic fever, by tonic spasms, especially on motion, followed by palsy, and often by delirium and coma.*

128. Although either of the membranes of the spinal cord may be primarily, or even separately and solely inflamed, yet the symptoms which more especially belong to the affection of each—which indicate either their separate or conjoint disease—cannot be distinguished in such a manner as to justify an attempt to form a diagnosis between them. That these membranes may be separately inflamed, although their conjoint affection is much more common, is often rendered manifest by the appearances observed after death, the pia mater displaying most frequently and most evidently the changes characteristic of inflammatory action.

129. *a.* The *dura mater* of the spinal cord is very seldom inflamed, unless as a consequence of injuries of the spine and disease of the vertebræ. In rare instances, however, I have found it inflamed in connection with acute rheumatism, the usual changes consequent upon inflammation of the membrane, and of fibrous tissues in general, namely, exudation on the inner free surface, thickening, and adhesion to the arachnoid, having been found after death.

130. After injuries and caries of the vertebræ, local or circumscribed inflammation of the dura mater has occurred. In these circumstances, effusion of fluid has been seen exteriorly to the membrane, or between it and the bodies of the vertebræ, with or without exudations from the arachnoid lining the dura mater, &c. These changes have been described by BERGAMASCHI, LALLEMAND, OLLIVIER, myself, and many others.

131. *b.* The *spinal arachnoid*, especially in its visceral layer, forms a sac, which does not adhere closely to the pia mater, as it does within the cranium. This visceral layer, and the sac within it, are the seats of the most serious lesions of the inner membranes of the cord — of both the *arachnoid*, and of the *pia mater* of the cord. Inflammation of the arachnoid—*arachnitis spinalis*—is rarely observed without inflammation of the *pia mater* of the cord, and the vascularity is much more manifest in the latter membrane than in the former. There is, however, one change often seen in the arachnoid alone that may be viewed as a consequence of repeated or protracted congestions, or of slight attacks of inflammation. This consists of dulness, opacity, and thickening of the arachnoid, and is usually combined with chronic effusion of serum into its sac, especially the inner sac. Adhesions between the arachnoid and dura mater are rarely seen, unless as a consequence of injuries.

132. *c.* Inflammation of the *pia mater* of the cord (*meningitis spinalis*) may occur spontaneously or primarily, but it is most commonly connected with inflammation of the other membranes — frequently a consequence of inflammation of one or both; and is generally occasioned by external injuries. Spontaneous inflammation of the pia mater of the cord is often associated with cerebral meningitis, and is then especially extended along the spinal cord. This complication is most frequent in infancy and early childhood. Inflammation of the pia mater is also commonly associated with inflammation of the substance of the cord with *myelitis*. I shall first notice acute spinal meningitis, subsequently the chronic states of the disease, and lastly, the complications which spinal meningitis often presents in practice.

133. *A.* ACUTE SPINAL MENINGITIS.—*a.* Acute inflammation of the membranes of the cord, when occurring as a *primary and uncomplicated malady*, generally commences with pain or soreness in the spine, with chills or rigors, and increased sensibility of the surface of the body. In other cases, the attack is more sudden and violent, with a sense of heaviness, pain, or uneasiness in the extremities. The pain is severe, and, although beginning in a particular part or region, generally extends more or less along the spine. The cervical region is most frequently attacked, especially in children, but the situation first affected depends much upon the cause in relation to the portion of the spine on which it acts. The pain is not confined to the spine, for all parts of the frame supplied with nerves proceeding from the portion affected, or its vicinity, are more or less subject to neuralgic pains, or uneasiness, tingling, and formication, accompanied with spasms, and with constrictions around the corresponding parts of the

trunk. These symptoms are always increased on motion, and in infants on their being moved, and when lying on the back on a warm bed.

134. When the cervical portion of the membranes is most affected, trismus, spasmodic retraction of the head, and tonic spasm of the spinal muscles, contraction or spasm of one or both arms, and twitchings or convulsive movements of the lower limbs, are commonly present. When the dorsal or lumbar portions are chiefly affected, painful constriction of the thorax or abdomen, increased pain on motion, with the other symptoms already mentioned, are present. In extreme cases the spasmodic contractions of the dorsal muscles recur, or are exacerbated, at intervals, and give rise to attacks of opisthotonos. Although the lower extremities are affected by pain, cramps, or clonic spasms, and are more or less enfeebled, the power of voluntary motion is not lost at an early stage; but it becomes much impaired, and ultimately abolished at an advanced period, and when the disease is not arrested in its usual course.

135. Febrile symptoms are always present; the pulse is hard, frequent, and constricted, or sometimes small; the heart's impulse is increased; the skin hot, acutely sensitive, sometimes perspiring freely; respiration is laborious, anxious, suppressed, or painful; the bowels are constipated; and the urine is suppressed or retained.

136. The above symptoms remit and recur at intervals, but they rarely intermit; and if the course of the disease be not arrested, they return with greater violence, the local symptoms evincing the extension of the disease along the spine, if it have commenced in any part of the column, until the paralytic affections become more and more general or complete, and until drowsiness, lethargy or delirium; irregularity, smallness or slowness of the pulse; involuntary evacuations, retention or incontinence, or alteration of the urine, and ultimately either asphyxia or coma, or both, supervene, and indicate the extension of the disease to the base of the brain, as well as the more or less complete abolition of the functions of the cord, by the products of inflammation of its membranes. A fatal issue may take place in four or five days, or from that time to two or three weeks, from the commencement of the attack.

137. *b. On examination after death*, the dura mater is generally found of a deeper colour than natural. The arachnoid is duller, more opaque, and somewhat thickened. The pia mater is reddened, injected, and swollen, especially in its posterior aspect. Fluid is effused between the membranes, especially between the pia mater and arachnoid, which is sometimes turbid, but more frequently coagulated, or in the state of coagulated lymph; or a purulent matter, occasionally mixed with a turbid serum or lymph, is sometimes met with. These changes may be limited to a portion of the cord, but they are more frequently extended more or less along it. The substance of the cord is often more vascular than natural. It is sometimes less vascular and firmer than usual, probably owing to the pressure occasioned by the effused fluids. It is not softened, unless the inflammation has extended into it.

138. *c. The association of spinal meningitis with cerebral meningitis—acute cerebro-spinal meningitis*—is more common than uncomplicated spinal meningitis, especially in infants and children. The disease may commence in either the spine, or within the cranium, and extend more or less rapidly from the one to the other. It rarely occurs co-etaneously in both. According to my experience, it most frequently commences in or near the base of the brain in children, extending downwards; and oftener in the spine in adults, advancing upwards to the brain. It has been observed, in both endemic and epidemic forms, in some parts of Ireland and France; and Dr. Wood refers to Drs. Hicks, Taylor, and Ames, who have described its occurrence, in these forms, in some districts of the south-western states of North America.

139. *Cerebro-spinal meningitis* commences, in the milder cases, with general uneasiness, a sense of fatigue, headache, pain in the neck and back, extending often along the spine, stiffness of the jaws, difficulty of deglutition, constipation, and retention of urine, or difficulty of micturition. As the disease advances, headache becomes more violent, and is attended by great sensitiveness of light and sound, by rigid spasms, retraction of the head and neck, acute sensibility of the surface of the body, by increased rigidity of the trunk, or cramps of the extremities on motion, and by convulsive movements of the limbs. The febrile excitement is great; the pulse is very frequent, constricted, or small; the skin is hot, thirst is urgent and constant, delirium supervenes, and is often preceded by vomitings.

140. In the severest attacks, chills or rigors, attended by severe pain in the abdomen and spine, and by vomitings and purging, are followed by reaction, and by all or most of the symptoms now enumerated in a more violent form. If the disease be not early arrested by treatment, more or less general paralysis and coma soon follow the above symptoms, and death ensues. The disease may run its course in forty-eight hours; but it much more frequently continues for six or seven days, and sometimes it may be prolonged to two or three weeks.

141. *d. On dissection*, the morbid appearances are said to have been comparatively slight, in some of the endemic or epidemic cases, vascularity and effusion not having been great, although more or less general, and the substance of the brain and cord not sensibly altered. More frequently, however, the changes have been remarkable, especially an effusion of greenish or yellowish lymph between the arachnoid and pia mater, which was scanty or nearly absent on the cerebral hemispheres, but much more abundant at the base of the brain, and in the spinal column, either investing the cord completely, or somewhat more abundant on its posterior aspect. It has sometimes extended along the whole cord to the extremity of the caudex equina, coating even the roots or commencement of the spinal nerves. This morbid exudation has not been found in the external sac of either the cranial or the spinal arachnoid.

142. *B.* Chronic Spinal Meningitis.—Chronic inflammation of the membranes of the spinal cord has hitherto been very imperfectly described and illustrated, and, as far as my own experience warrants the statement, it is certainly not so rare a malady as stated by several recent writers. It may occur as a consequence of an acute or sub-

acute state of spinal meningitis; but I have observed it much more frequently as the primary disease, upon which an acute or sub-acute state supervened sooner or later, or as the disease extended upwards to the medulla oblongata, or base of the brain. The earliest account of a case of chronic spinal meningitis, with the appearance after death, was recorded by myself in 1820; and since then I have seen a considerable number, and examined the bodies of several of them.

143. Whilst the morbid appearances in the cases of acute spinal meningitis have been such, as far as I have observed them, as to indicate the chief seat of morbid action to have been the inner sac of the arachnoid, or between the arachnoid and pia mater, the changes in chronic spinal meningitis have shown the external cavity or sac to have been their principal or only seat, effusion of coagulable lymph between the arachnoid of the dura mater and the visceral arachnoid, obliterating the cavity by adhesions of the opposite surfaces by this medium. This diversity may depend upon the circumstance of the disease assuming not only a more acute, but a more rapidly diffusive character when the inner arachnoid is attacked, or when the fluid is effused between the arachnoid and pia mater, than when the disease commences, as it probably does in chronic cases, either in the dura mater, or on the arachnoid covering it. Chronic meningitis may follow the acute form, or be produced by any of the causes about to be assigned.

144. *a*. The *causes* of chronic spinal meningitis are the causes of spinal maladies generally (§§ 16. *et seq.*), but they are more especially blows or falls on the spine, particularly on its lower regions; currents of cold air, after having been over-heated, directed on the spine; sprains or bruises of the column; sleeping in damp beds, or upon the ground; the abuse of alcoholic liquors; venereal excesses; the extension or metastasis of rheumatism to the membranes and ligaments of the spine; the congestion of the spinal membranes during continued and eruptive fevers; caries of the vertebræ; and various organic changes implicating the cord or the membranes.

145. *b*. The *symptoms*, especially the initiatory symptoms, vary much, according to the cause, to the temperament, habit of body, and age of the patient, and to the region of the spine primarily affected. Whatever part may be first attacked, the tendency to spread, or to extend upwards, as well as downwards, should not be overlooked; for, although this tendency is not nearly so remarkable as in acute spinal meningitis, yet it exists more or less. It may not be remarked for months, or even for years, in the more robust and otherwise healthy subjects, the patient hardly presenting any increase of ailment, or even becoming greatly relieved; but more frequently, especially in delicate or cachectic persons, or during an injudicious treatment, the symptoms extend and become aggravated, more or less rapidly, and either pass into a sub-acute or an acute state, or indicate the extension of the inflammatory action to the base of the brain. This aggravation and extension of the malady are favoured by a recurrence of the causes which first induced it, by mental perturbation, by physical exertions, attended by sudden or frequent movements of the spine, by measures which lower the powers of life and of vital resistance, by imperfect attention to the digestive, secreting, and excreting functions, &c.

146. Chronic spinal meningitis generally comes on slowly and insidiously; and, owing to many of the most severe symptoms being experienced in parts far removed from the spine, it is often, at early periods of its course, mistaken for chronic rheumatism, for neuralgia, or for simple weakness of the limbs, or even for atonic gout. As it proceeds, it may be viewed as a form of rachialgia or spinal irritation, or as an attack of chorea, either of which may be followed by, or pass into, chronic spinal meningitis, at some period of their course, even if they should not prove identical with the early progress or commencement of chronic inflammatory action in the spinal membranes, or with congestive states of these membranes, upon which the inflammatory may supervene.

147. The patient complains of aching, or of dull pains in some part of the spine, generally connected with pains in the nerves, or in their extremities, corresponding with the part of the spine affected; or with pains in the extremities; or with formication, tinglings, prickings; or with a combination of these, with some degree of numbness in the lower limbs. The pain in the lower extremities is sometimes most poignant, especially in certain positions or movements; is occasionally absent, or intermittent, or remittent; and is succeeded during the intermissions by uneasiness in various forms. The gait of the patient becomes now weak, unsteady, and tottering. He moves with difficulty or uncertainty, and staggers or straddles when he attempts to walk. If the disease extends to the dorsal and cervical regions of the cord, a similar difficulty and irregularity of motion are observed in the hands. The fingers imperfectly perform their office; their motions being irregular, slow, and difficult, and articles being held by them awkwardly and insufficiently. The movements of the arms are irregular or in jerks, so that the patient is either nearly or altogether incapable of feeding himself. He may continue in this state for months, or even years. One gentleman whom I attended was nearly, as now described, for seven or eight years, experiencing various exacerbations, but always suffering more or less, the disease having all this time affected the whole spine to above the nape of the neck, and being attended, as it usually is, by spasmodic contractions in various muscles, and distressing constrictions around the abdomen and thorax. During this state of the malady, flatulence of the stomach and bowels, anorexia, costiveness, or marked irregularity of the bowels, incontinence of urine, dryness of skin, or occasional sweats, and aggravation of the symptoms during the night, or when warm in bed, are more or less experienced.

148. During the progress of the disease, the pulse may not be materially affected, especially when the lower regions of the cord are chiefly or solely affected. But when the membranes of the cervical portion of the spine are attacked, the pulse is often very slow, and the actions or impulse of the heart disordered. Palpitations are frequent when the dorsal region is more acutely implicated. Difficulty of deglutition, slowness, or irregularity of respiration, spasm of the muscles of the neck, with paralysis of one or both arms, or

irregular motion, or contractions of the arms, often supervene, particularly as the disease extends upwards to the cervical membranes. Ultimately the paralysis becomes complete, especially the power of motion, at first in the form of paraplegia, and, if not arrested, passes into incomplete or complete general *paralysis* (see that article, §§ 69. *et seq.*). With the progress of paralysis, impaired animal heat and nutrition, a disposition to form gangrenous sores in parts pressed upon, and the several phenomena described under that head supervene. At last the lesion of the membranes extend to the medulla oblongata and base of the brain, and life is terminated by asphyxia, or more slowly by coma, supervening on delirium. In some cases the chronic affection of the lumbar or dorsal spinal membranes, after a protracted continuance or even after a marked improvement of all the symptoms, is unexpectedly followed, or after evident causes, by an acute attack, extending upwards to the cervical region, or to the base of the brain, and more or less rapidly causing dissolution. Of this course of the malady, I have met with several instances. A few of these have been noticed under the article Paralysis, in the chapters on *Paraplegia* and *General Paralysis* (§§ 48—74.); others have occurred to me since that article was written.

149. *c. Chronic spinal meningitis following the acute.*—A medical friend was driven, after having been over-heated, during a cold night, to some distance in an open carriage. He was soon afterwards seized with pain in the lower dorsal and lumbar spine, with spasmodic contractions of the lumbar muscles, and with most acute pain and cramps in the lower extremities. I did not see him until several weeks after the commencement of this acute attack. He then complained of extremely severe rheumatic pains in the lower limbs, with increased sensibility of the surface, a nearly total loss of motion of the lower extremities, of tenderness on pressing the spinous processes of the upper lumbar vertebræ, of a girding sensation proceeding thence around the abdomen, with occasional cramps and paroxysms, of pains in the thighs, legs and feet. His bowels were costive; his urine was voided regularly; but it contained much of the phosphates. The disease was viewed as acute rheumatic inflammation of the membranes of the cord, which had passed into a more mitigated and chronic form; and it was inferred that coagulable lymph was effused between the membranes, the patient having continued paraplegic. Another medical friend, whom I soon afterwards attended, for some time with Dr. Watson and Sir B. Brodie, was similarly attacked. The urine was freely voided, but it abounded with the phosphates. In the course of our attendance, inflammation of the femoral veins supervened. This complication was, however, overcome; but the spinal disease became chronic. This case was also caused by exposure to cold after being over-heated, and was viewed as rheumatic.

150. *d. Chronic spinal meningitis; lymph between the membranes, partially converted into adipose substance.*—A female, aged about fifty, very corpulent, complained of pain in the dorsal spine, and loss of the power of motion in the lower extremities, with tenderness on firmly pressing on the spinous processes of the lower dorsal vertebræ, and with spasms of the muscles of the lower limbs. The loss of motion was gradual, was preceded by spasms and increased sensibility, and was more complete in one limb than the other, but it slowly became complete in both. There was no loss of sensibility. The bowels were costive, the urine was sometimes retained, but subsequently was often passed involuntarily. A distressing feeling of constriction around the abdomen was complained of. After some months the voluntary motions of the lower extremities partially returned, and the excretion of urine was more under command; but some time afterwards the pain in the spine extended upwards, the constriction being then referred to the thorax. One arm soon afterwards became partially paralysed, and she soon afterwards died of asphyxia. She had imputed her attack to exposure of her back to a current of cold air when insufficiently clothed; but her habits were very intemperate. On examination after death, the venous sinuses of the vertebral canal were remarkably congested with black semi-fluid blood. Coagulated lymph, partially organized, was effused between the dura mater and visceral arachnoid; and the more organized portions presented an adipose appearance, from the quantity of oil-globules they contained. The upper portion of the cord and medulla oblongata were very vascular, and surrounded by a turbid serum and recently effused lymph.

151. The inflammation in this case, after being limited for many months, in a chronic form to the membranes of the lumbar and dorsal portions of the cord, ultimately extended upwards in a more acute form to the membranes of the cervical medulla and the medulla oblongata; the effusion of lymph from the inflamed and congested membranes in these latter situations having been the more immediate cause of death. The oleaginous change, or approach to a fatty degeneration of the more organized portions of the coagulated lymph, observed in this case, was still more remarkable and complete in the following.

152. *e. Chronic spinal meningitis supervening upon prolonged jaundice; lymph effused between the membranes, and converted into a soft, adipose tissue in the dorsal and lumbar region.*—A lady, aged about fifty at her death, was attended by Dr. King, of Eltham, and the author, for jaundice, which had continued for several years, without having been materially influenced by treatment. She had, however, retained her strength, flesh, and spirits, and was able to go abroad daily, until nearly a twelvemonth before her death, when she gradually lost the motive power of her lower extremities, sensibility having been unimpaired. She had, previously to, and about the accession of, the palsy, complained of pain in the lower dorsal and lumbar spine, with constriction around the abdomen. The bowels were costive, but the excretion of urine was not materially affected. The menses were regular, and continued so up to two or three months before her death. The palsy had continued for many months, with a slight improvement during the latter months, when a few days before her death, and owing to mental and physical perturbation, signs of the extension of the spinal meningitis, in an acute form, to the cervical portion of the cord, and to the base of the brain appeared, with paralysis of the upper extremities, delirium, and coma.

153. On examination after death by Dr. King

and two other medical men, in my presence, the dorsal and lumbar spinal membranes were found agglutinated by a substance, which presented an organization almost identical with adipose substance, but which, as it approached the upper portion of the dorsal region, presented more and more of the characters of firmly coagulated, or partially organized lymph; and, in the cervical region, as far as the base of the cranium, the lymph had the usual appearance of recent effusion, and was attended by a considerable accumulation of turbid serum. In this case, as well as in others where I have observed coagulated lymph many months after its effusion between serous surfaces, the conversion of it into an adipose, or rather into a cellulo-adipose tissue—a more or less fatty degeneration of the coagulated or organised lymph—had been effected, this conversion being in some respects a process of reparation, admitting of a partial return of the functions of the diseased parts (see *Of the Causes, Nature, and Treatment of Palsy, and Apoplexy*. By J. Copland, M.D., F.R.S. &c. London, 8vo. pp. 60. *et seq.*)

154. ii. Inflammation of the Spinal Cord. —*Myelitis*, from *μυελος, the medulla spinalis.*—*Myelite*, Fr.—*Markentzündung*, Germ.—Inflammation of the substance of the spinal cord may be *acute* or *chronic*, as observed in spinal meningitis, and it may occur primarily and simply, but it is more frequently associated with inflammation of the pia mater of the cord, often extending also to the visceral arachnoid. The frequency of these associations —the extension of the inflammatory action from the one structure to the other—and the circumstance that the disease rarely comes under the eye of the physician until it is advanced in its course, render the early history of myelitis difficult to be described. The older writers on medicine appear to have been unacquainted with this disease; and it is only since pathological anatomy was advanced by comparatively recent inquirers, that the disease of the spinal cord, and of its membranes, have received any attention, very much still requiring to be ascertained respecting the extent of function and the lesions of this part of the nervous system, and the signs and symptoms by which these lesions are manifested during life. Among the several writers of the present day who have noticed the diseases of the spinal cord, very few have endeavoured to distinguish the symptoms which are proper to inflammation of the cord, from those which more especially belong to inflammation of its membranes; and the signs, which some writers have assigned to the one disease, have been by others attributed to either.

155. *A. Acute Myelitis* commences, with or without chills or rigors, with acute, deep-seated pain in some portion of the spine that is much aggravated by motion. J. Frank, however, says, that he has not observed this exasperation of the pain on motion. I have remarked it, but not always. The patient lies sometimes on the abdomen, sometimes on either side, but he cannot lie long on his back on a soft and warm bed. According to Klohss, this last position may be much longer retained on a hair mattress. The spinal pain is generally more or less limited in extent, and is attended by stupor, or numbness and prickings or tinglings in the corresponding muscles and limbs. The stupor is the more marked the more violent and rapid the inflammation, and the sooner terminates in more or less complete palsy. In some cases the patient cannot move his lower extremities, which are the seats of excessive pains, exasperated most acutely by the slightest contact. M. Ollivier and myself have seen the pain and sensibility so excessive as to render the contact of the bed-clothes unbearable. The retention of the fæces and urine is at first more or less complete, but their involuntary excretion is very common as the disease advances. In rare cases, or when the malady is very rapid, the alvine discharges are involuntary from the beginning. Occasionally, however, constipation continues throughout, and excretion of urine remains under the control of the will.

156. The paralysis consequent upon myelitis sometimes ascends from the lower extremities until it reaches the superior parts of the trunk, and even the superior members, causing death by affecting the respiratory nerves, and producing asphyxia. In rare cases, the disease proceeds in an opposite direction, extending from above downwards. In some instances, there is only loss of motion, sensibility being slightly or not at all impaired. In others, sensibility alone is abolished; and in several, there is loss of both motion and feeling to an equal extent. These differences are owing to the parts of the cord affected. It was formerly believed that the anterior columns, presiding over motion, were affected when motion was lost, and that the posterior, presiding over sensation, were affected when sensibility was lost. Several cases, however, recorded by Rullier, Stanley, Webster, and others, prove either that the changes observed in the posterior columns of the cord have taken place at the moment of, or immediately after dissolution, or that sensation may be transmitted through other channels besides these columns, or even independently of the spinal cord itself. But this subject has been sufficiently discussed in the article Paralysis (see §§ 179, *et seq.*). It may, however, be here remarked, that in the cord, as in the brain, the white or fibrous structure may be more especially connected with motion, the grey structure with sensation and its several manifestations. Usually paralysis commences in a single limb, and afterwards extends to the opposite side. Sometimes spasms, contractions, or convulsions of various duration, precedes the paralysis. When palsy is complete, the limb is flaccid as well as motionless, but when less so, permanently contracted and painful.

157. Myelitis seldom is seated in the whole extent of the cord; much more frequently in a portion only, the symptoms generally indicating the seat. If it be in the vicinity of the annular protuberance, disorder of the senses, or furious delirium, or many of the symptoms of inflammation of the brain, and even hydrophobic symptoms, followed rapidly by general paralysis and asphyxia, are often observed. If the cervical portion is affected, there are pains in the neck, and generally rigidity of the muscles of the neck and of the upper extremities, which are sometimes convulsed or contracted, and at last paralysed. The palsy usually commences in one of these extremities only, and is preceded by numbness and prickings, at first at the points of the fingers, rising gradually, thence to the hand, fore-arm, and arm, and is soon replaced by loss of motion, and often

also by more complete loss of sensation. Respiration is generally laborious, painful, anxious, and performed chiefly or only by the diaphragm. M. OLLIVIER and myself have observed difficulty of deglutition at an advanced stage, this function being often painful also, especially when swallowing fluids. Singultus is also sometimes observed.

158. When the inflammation is seated in the dorsal portion of the cord, or between the two thicker portions, giving origin to the nerves of the extremities, then continued or frequent successions of the trunk of the body, not extending to the limbs, are observed. If the thicker portions of the cord are affected, the convulsive movements extend to the limbs whose nerves originate in these portions. Respiration is short, precipitate, and performed by the diaphragm: there are likewise palpitations, and strong, frequent or irregular action of the heart. To these symptoms, according to the younger PINEL, there are joined a nearly entire abolition of the functions of the nerves originating in this part of the cord, and a state of febrile excitation of the other functions. When the lumbar portion of the cord is affected, spasms or constriction, or contraction of the abdominal muscles, paralysis of the lower limbs, involuntary stools, or retention of the urine and fæces, with deep-seated pain in the lumbar spine, are observed. Sometimes priapism occurs, especially when myelitis is caused by a fall or injury. The *duration* of acute myelitis may vary from three or four days to as many weeks; and various febrile and sympathetic phenomena may attend individual cases; as vomiting, singultus, dyspnœa, delirium, morbid states of the urine, and a disposition to bed-sores, especially in the more prolonged cases, &c. (see art. PARALYSIS, §§ 64. *et seq.*).

159. *B.* CHRONIC MYELITIS may follow the acute, which, owing to treatment or other influences, may become chronic and slight, or subacute and ultimately chronic; or it may commence in a slight and chronic form, and after an indeterminate period, becomes more or less acute and rapidly fatal. The symptoms are chiefly a less intense state of those characteristic of the acute. There are generally pain, more or less slight or severe, in some part of the spine, and pains or cramps in corresponding muscles or limbs, for some time before loss of sensibility, or of motion, takes place. The paralytic symptoms may, however, be preceded by so little suffering as not to interest the patient, or come under the cognizance of the physician. There is seldom much tenderness upon pressing the spine, or increase of pain upon percussion of, or when pressing, the spinous processes. After a time, and sometimes without much previous disorder, simple diminution of sensibility or of the power of motion is experienced. This increases slowly. The patient is subject to tremor. The gait becomes uncertain, staggering, or tottering. He lifts and directs the extremities with difficulty, and uncertainty. Ultimately the limbs no longer can support the body. Involuntary startings of the muscles, subsultus, or rigid contractions of muscles or limbs occur. The paralysis ascends to the trunk, affects the excreting functions, and implicates in some degree the circulating and vital functions. The pulse becomes slow, irregular, or weak; the limbs flabby, œdematous, and cold; sloughs form on parts which sustain pressure. The urine is morbid, retained, or passed involuntarily, abounding in the sulphates and phosphates; and ultimately dyspnœa, coma, and death by exhaustion or by asphyxia takes place.

160. *C. Appearances in fatal cases of Myelitis.*—These consist chiefly of red softening of the cord in various degrees. It may extend through all the columns of a small portion of the cord, or along a large portion, and it may vary from a slight diminution of consistence to complete diffluence of the structure. It may affect only one or more columns, or it may be limited to either the white or to the grey structure, or it may extend to both. The softening is often yellowish, or presents merely a slightly red or pinkish shade. The changes in the cord may exist alone, or be associated with inflammatory changes in the pia mater and visceral arachnoid; much more rarely with changes between the dura mater and visceral arachnoid.

161. ROKITANSKY remarks that, in the cord, as in the brain, inflammation attacks sometimes the white structure, sometimes the grey substance, occasionally both together. But myelitis of the grey substance exists in long streaks, or in the whole extent of this substance, restricting itself to this structure, and producing a peculiar condition of the cord, as well as the increase of volume, which attends softening, and a peculiar form of dropsy, in which it occasionally terminates. Red softening of the grey substance is tinted according to circumstances, of a chocolate brown, or plum colour, or rusty brown, or yeast-yellow, and corresponds with the central softening of the spinal cord, described by ALBERS. In *chronic cases* of myelitis, yellow softening of the columns, and condensations or indurations in various grades and extent, have been observed. Indurations, conjoined with atrophy, chiefly of the white columns, have also been remarked.

162. M. CALMEIL, who has paid much attention to diseases of the spinal cord, states in relation to the comparative frequency of softening in the different regions, that, in twenty-five cases, six existed in the cervical region, eleven in the dorsal region, five in the dorso-lumbar, and two in the lumbar. In one case only was the organ softened throughout. In one instance, the left half of the cord only was softened; in two the anterior columns were alone thus altered. The softened nervous structure preserved its natural colour in ten cases. It presented a yellow tint in six; a rose tint in four; a red colour in three; and a brown hue in one. The softened molecules were mingled with blood-globules in one. The pia mater was brown in one case; was injected and red in seven, and covered by false membranes in two instances. It may here be remarked, that the white and yellow softening does not necessarily proceed from inflammation; but as it gives rise to nearly the same symptoms as the inflammation, the difficulty of separating them is great.

163. iv. DIAGNOSIS.—*A.* It is of much importance to distinguish between *rheumatism* and inflammation of the spinal cord or of the membranes. The pain both in the spine and in the corresponding nerves, or in muscles supplied by these nerves, will not be mistaken for primary rheumatism if this very correspondence be attended to, and if the girding or sense of constriction in the corresponding situations of the trunk be considered.

The history of the case will also assist the diagnosis. It should, however, be recollected, that rheumatism may either extend or occur as a metastasis to the membranes of the cord. This has been supposed to be a very rare occurrence; but, according to my experience, although not frequently observed, it is by no means rare. When, however, it takes place, it is essentially inflammatory, assuming the sub-acute or chronic states of spinal meningitis, and hence no distinction is to be made between them in nature or treatment. It is only when rheumatism, in its usual forms, attacks parts in the vicinity of, or in nervous connection with, the spine, that the diagnosis is of importance. The spasms, the deep-seated burning sensation in the course of the spine; the tonic contractions of the muscles of the back, curving the trunk backwards; the altered sensibility of the surface, with numbness or prickings in the extremities; the stupor or loss of motion will distinguish spinal meningitis and myelitis from rheumatism, which is unattended by cramps or tonic spasms, or by the constrictions or girdings of the trunk already mentioned. In the former, also, pressure or percussion, or pressure conjoined with heat, over the spinous processes, sometimes increases pain; but in the latter, pain is increased by pressure on the sides, or in the vicinity of these processes, and by motion of the affected parts.

164. *B.* The diagnosis between *spinal meningitis* and *myelitis* is much more difficult, inasmuch as the former generally influences more or less the functions of the cord, and inflammation of the visceral membranes of the cord is often associated with myelitis. Spinal meningitis, however, has a marked disposition to extend itself, and is frequently complicated with cerebral meningitis, especially in children, whilst myelitis is generally limited to a portion of the cord only. Acute spinal meningitis may, with much certainty, be inferred from three symptoms: the first is a general contraction of the muscles of the back, varying from simple muscular rigidity to violent spasm, or tetanic rigidity, occasioning complete opisthotonos. In meningitis of the base of the brain, the head is thrown backwards, or the cervical portion of the spine is sometimes retracted; but the trunk preserves its form. The second symptom is the violent pain extending more or less along the whole spine. The third is the continuance of sensibility even of the limbs, although motion may be abolished by the pressure of effused lymph on the cord and roots of the nerves.

165. The febrile symptoms are more marked or more severe in spinal meningitis than in myelitis; and paralysis of motion either does not occur, or not until effusion disorders the functions of the cord, or until inflammation extends to the substance of it. In myelitis the pain is not so severe; and the most remarkable symptoms are, impairment or loss of motion, and diminution of sensibility. In chronic myelitis, the membranes often become similarly, or even acutely affected, the symptoms most characteristic of both spinal meningitis and myelitis being present.—*Spinal Apoplexy* (§§ 192. *et seq.*) is to be distinguished from both these diseases by the sudden accession of the severe symptoms, and by the rapid occurrence of the paralysis of motion, and generally also of sensation.

166. v. COMPLICATIONS.—Spinal meningitis may be associated with myelitis, and, in such cases, the symptoms of the one will be accompanied with those of the other. This complication is often a consequence of severe injuries; retention of urine, priapism, paraplegia, &c., frequently being present, according to the seat and severity of the injury (see art. PARALYSIS, §§ 50. *et seq.*). One or both these diseases may be further complicated with inflammation or caries of the vertebræ, or of the intervertebral substance; or with aneurism of the aorta, or with spinal apoplexy, or with some one or other of the organic changes implicating the spinal cord or its membranes, about to be noticed (§§ 178. *et seq.*). Spinal apoplexy, when it fails of producing death in a very short period, is generally followed by spinal meningitis or myelitis, according to the seat of the sanguineous extravasation. The complication of spinal meningitis with cerebral meningitis has been sufficiently noticed above (§§ 138. *et seq.*).

167. vi. PROGNOSIS.—*A. Acute spinal meningitis* is a dangerous disease, and the association of this with cerebral meningitis is still more dangerous, although not necessarily fatal when actively treated at an early stage. Chronic spinal meningitis, when it has advanced so far as to cause paralysis, is seldom altogether removed; but the symptoms, both paralytic and spasmodic, may be considerably ameliorated, whether it has occurred as the primary malady, or followed the acute. At all periods during the course of chronic spinal meningitis, an acute extension of the disease, generally upwards to the base of the brain, may occur, especially upon exposure to any of the causes of the malady, or even after any physical or mental perturbation, and carry off the patient. I have observed this to take place in chronic cases, even of ten or twelve years' continuance. In some cases, the disease may advance slowly for many years; in others, it may be stationary for as long a period; and in a few, an amendment more or less considerable takes place. It is chiefly before the supervention of paralysis that treatment is most efficacious; and even in this early period the best devised means often fail: much depends upon the constitution, habits of life, and previous ailments of the patient. Whilst writing this, a gentleman whom I attended nine years ago for acute spinal meningitis, affecting chiefly the cervical and dorsal regions, called upon me. He had been seen also by Drs. CHAMBERS and BRIGHT, in consultation with myself. His habits had been irregular, and the acute attack passed into the chronic, with paralysis of motion, which was more remarkable in one side than the other. The painful symptoms have long since ceased, and the paralysis is considerably less.

168. A lady, aged about forty, and very corpulent, was seized with acute spinal meningitis and suppression of the catamenia. She had had several children. The disease had existed three or four years when I was requested to see her. Paralysis of motion was complete from the neck downwards, but sensibility was not impaired. Her spirits were good, and she still retained considerable power over the alvine and urinary excretions. She possessed only a very slight power of motion in one arm. Treatment similar to that about to be advised for the chronic form of the disease (§§ 173. *et seq.*) was prescribed. She recovered gradually: could use both hands, and walk abroad.

She went on the continent; after some time she proceeded to the north of Scotland to the family seat, and continued in comparatively good health for a long time. She had, whilst at her residence in the north, what was supposed to have been an attack of fever, of which she died. It is more probable, from the presence of cerebral symptoms in her case, that an acute extension of spinal meningitis had supervened, and implicated the membranes of the base of the brain, and thereby proved fatal, as I have uniformly observed when the malady was thus extended.

169. A respectable tradesman complained of chronic spinal meningitis, consequent upon a fall on the lower part of the back, attended by partial paralysis of motion in both lower extremities, and constriction around the abdomen. I saw him occasionally for some years, during which time he was able to walk about with the assistance of a stick, or of the arm of a servant. After a time I was requested to see him, and was informed that he had called to his aid an irregular practitioner, who had confidently promised to cure him, and that he soon afterwards became much worse, complaining of spasms, and of severe pain along the whole course of the spine. He was delirious and generally paralysed when I now saw him; but was soon afterwards comatose. A gentleman, aged about forty, gradually became affected, as described under the head of chronic spinal meningitis (§§ 159.). Sensibility was not diminished, but voluntary motion was remarkably impaired in all his limbs. The bowels were always costive, and the power of retaining the urine was very much lessened, and ultimately lost. Still a full dose of opium or morphia enabled him to retain it from six to ten hours. He lived in this state for about twelve years. He afterwards became much worse, was feverish, delirious, and comatose, in succession. I examined the body of both these persons after death, and found the changes, as already described (§§ 160.). The spinal cord appeared somewhat atrophied. Recent inflammatory appearances were observed in the membranes of the base of the brain and medulla oblongata in both.

170. *B. The prognosis of myelitis*, when *acute*, is generally most unfavourable, death often taking place in a few days, even although the treatment may have been both prompt and judicious. The *chronic* form is less unfavourable. It may continue for months, or even years, when limited in extent; or the patient may even recover partially. In these cases, it may be inferred, that the resulting lesions have either been slight, or at least partially removed, so as to admit of the continuance of life for an indefinite period. An exasperation of the disease is, however, apt to take place when exposed to causes of physical or mental perturbation. Although but little hope can be entertained of effecting a cure, when confirmed paralysis exists, yet we may be more sanguine as to the result at any early stage. When, however, the powers of life are evidently sinking; or when the urine is very morbid in its constitution, or as regards the functions of excretions; or when the influence over the sphinctures is lost, or especially when sloughs form on parts which sustain the pressure of the body, then hopes of sustaining life much longer cannot reasonably be encouraged. The danger is always greater when the cervical or dorsal portions of the cord are affected, than when the lumbar region is attacked.

171. vii. Treatment.—The treatment of inflammation of the membranes of the spinal cord, and of the cord itself, varies much with the acuteness, the duration, and the special characters of individual cases, and with the constitution, state, and circumstances of the patient.—*A. Acute spinal meningitis* requires very prompt and energetic means; for, if the disease proceeds so far as to occasion its usual changes, the best devised means will often prove inefficacious. Bloodletting, general or local, or both, according to the habit of the body, strength, and age of the patient, is necessary, especially very early in the attack. The amount as well as the repetition of the bloodletting, should depend upon the circumstances just mentioned; but I have generally preferred the application of cupping-glasses along the spine, followed by terebinthinate epithems or embrocations. The bowels should be freely evacuated; and this intention may be accomplished by the immediate administration of a full dose of calomel, or of calomel and James's powder; and within a few hours afterwards by the infusion of senna, or other aperients, which ought to be repeated until the desired effect is produced. Terebinthinate enemata are always beneficial, not merely in procuring a full evacuation of the bowels, but also in presenting the changes usually following acute inflammation of serous membranes; and hence the spiritus terebinthinæ may be given with benefit by the mouth; for when thus exhibited, and in such a mode as will not excite vomiting, it is more certain and prompt in preventing the effusion of lymph from these membranes, than the free administration of mercury.

172. Besides the above, various other means have been advised by writers, especially very deep incisions on each side of the spinous processes by Goss; the cold affusion, or the application of ice, along the spine by Ollivier, and the warm or vapour bath by others. Cupping and scarification, or dry-cupping, when the former is no longer required, should be preferred to the first of these; the benefits or the effects produced by the second have not been shown, and the advantages produced by the third are very equivocal. Warm pediluvia and manuluvia, salt and mustard, having been added to the water, are generally of service. But after the satisfactory operation of the means advised above, the due consideration of what should be avoided may be of more service than the employment of means of doubtful efficacy. The patient should lie on a hair couch, on either side, so as to keep the spine moderately cool, and allow the application and renewal of such agents to it as have been advised. Vomiting, straining at stool, and motion, should be prevented as much as possible; and if the urine be not duly evacuated, it should be drawn off frequently, care being taken not to allow an accumulation of it in the bladder for any considerable time. Cooling diaphoretics or refrigerents are always of service as long as febrile symptoms continue. Blisters are rarely of service, but are oftener productive of irritation of the urinary passages. Terebinthinate epithems or embrocations, such as I have advised in various parts of this work, or a combination of these with opium—the tincture, wine, &c.—

are very frequently of use, and may be repeated daily, or twice in the day. If the pain and sympathetic affections of spinal meningitis continue, notwithstanding the means above prescribed, the tincture or extract of *aconite* will often prove of much service, when exhibited in sufficient doses.

173. *B.* If *chronic spinal meningitis* either follow the acute or occur primarily, certain of the means already mentioned may be cautiously employed. In some instances, scarification and cupping, or dry-cupping, or a repetition of these, may be still resorted to, especially at an early stage of the primary chronic, or during the insidious commencement of the disease. The intestinal and urinary evacuations always require attention. Various counter-irritants have been advised, especially blisters, issues, moxas, setons, tartar-emetic ointment, the actual cautery, &c. I have very rarely seen either blisters, or setons, or issues, or the tartar-emetic ointment, of any service in this state of the disease. Of moxas and the actual cautery, I have not had sufficient experience. Dr. BENNETT states, that he has seen the latter agent produce a cure in two cases of chronic spinal meningitis occasioned by diseased vertebræ. It is most probably in this complication, that the actual cautery, setons, issues, and moxas are most likely to be of benefit. In other circumstances of the disease, the terebinthinate embrocations or epithems along the spine, or the frequent sponging of the surface of the spine with a strong solution of bay salt have been more serviceable, according to my experience, than either of these.

174. In chronic spinal meningitis, I have not found lowering measures of much service, especially when far advanced or of long standing; and when it has produced paralysis, owing to the changes consequent upon inflammatory action, I have generally prescribed such means as seemed most likely to support vital resistance to the extension of the disease, and at the same time to remove the structural alterations which may have already been produced. With these views I have given small doses of the bichloride of mercury, with hydrochlorate of ammonia, and either the decoction or the tincture of cinchona, and the fluid extract of sarza; and after this combination has been continued for a considerable time, but with strict reference to its effects, I have substituted the iodide of potassium and the carbonate of potash, or liquor potassæ, or BRANDISH's alkaline solution, for the bichloride and the ammonia, the other medicines being continued in conjunction with the iodide and fixed alkali.

175. *C. The complications* of either the acute or the chronic state of spinal meningitis clearly demand means such as have been advised. When acute cerebral meningitis is associated with the spinal disease, the best devised means are generally inefficacious, but those already prescribed appear the most appropriate. The complication of chronic spinal meningitis with rheumatism requires the same indications of cure, and similar means to those noticed above (§§ 171. *et seq.*). But in this state of the disease, as well as in certain other chronic complications or forms, medicated warm baths, especially such as contain stimulating substances, deserve a cautious trial; and if they be found of the least service, they should be sufficiently tried. In one case in which the spinal malady appeared in the course of very prolonged jaundice (§ 152.), the more severe symptoms were somewhat mitigated, notwithstanding the persistence of the primary disease. The association of spinal meningitis with disease of the vertebræ, or of the cord itself, has been treated by me, according to the principles now enunciated; and I have no experience of any other means, than those already noticed, which appear to be of any service in those or other complications of the malady.

176. *D. Acute Myelitis* requires similar means to those already advised for acute spinal meningitis; but, even at an early stage, vascular depletion is not so beneficial, and admits not of being so freely employed in the former as in the latter. The other means, especially the internal medicines and the external applications, particularised above, may be resorted to. In addition to these, urtication, warm baths containing stimulating and rubefacient substances, anodyne and terebinthinate embrocations along the spine, and the preparations of aconite when spasm or pain is urgent, may severally be employed. The paralytic symptoms, which are generally much earlier and more complete in myelitis than in spinal meningitis, may be combatted by the bichloride of mercury, or by the iodide of potassium, and the other remedies, as combined above (§ 174.). The preparations of *nux-vomica* or *strychnine* have been recommended, and too frequently and injuriously employed in these cases. In all cases which may be inferred, from the mode of attack, or from the characteristic symptoms, to be either acute or chronic myelitis, we have few, and oftener no, means of ascertaining the nature of the changes which have taken place in the cord and its membranes; and hence those preparations, especially strychnine, which excite or irritate the spinal cord, should, if prescribed at all, be exhibited with great caution.

177. *E.* In the more or less *chronic* states of myelitis, various means have been tried, but rarely with more than very temporary relief. In these states especially, the preparations of nux vomica, of strychnine, of arnica, phosphorus, &c.; electricity, galvanism, electro-magnetism; frictions, with various stimulants and irritants, and external derivatives, may severally be resorted to, according to the peculiarities of the case, but they require both discrimination and caution. It is only in the more protracted cases of either myelitis, or spinal meningitis, where the symptoms indicate passive, rather than active disease—when neither acute nor painful symptoms are present, that these means should be employed. Farther remarks on the use of these and similar means, will be found in the article PARALYSIS (see §§ 244, *et seq.*), and in my work on *Palsy and Apoplexy* (see p. 397. *et seq.*).

VIII. STRUCTURAL CHANGES OF THE SPINAL CORD AND OF ITS MEMBRANES.

CLASSIF. — IV. CLASS. — III. ORDER (*Author*).

178. i. MORBID STATES OF THE SPINAL MEMBRANES. — The *dura mater* of the spinal cord is unprovided with the granulations called Pacchionic glands. It is not so firmly attached to the bones as that of the brain, and the arachnoid and pia mater are more loosely united to the cord than these are to the brain. Owing partly to these circumstances, diseases of the spinal bones less frequently affect their contained structures, than those of the cranium.

179. *A.* The membranes of the cord are sometimes *distended* by fluid, *discoloured*, and present various grades of *consistence*, but not so frequently as those of the brain. *Irritation*, vascular *erethism*, and *congestion* often are observed, especially in continued fevers, in the exanthemata, in tetanus, in rabies, in spinal epilepsy, convulsions, gout, rheumatism, &c.; but these are not to be confounded with true *inflammation*, which, however, may occur as an epi-phenomenon in these diseases. All the alterations consequent upon inflammation of the membranes of the brain are observed after spinal meningitis, as effusions of *plastic lymph*, or of *serous*, or *sero-albuminous* or *puriform fluids*, *thickening*, *induration*, *agglutination*, and partially organised *adhesions* of the membranes, *cartilaginous* and *ossific deposits*, and much more rarely *ulceration* and *mortification*. *Tubercular* formations, *tumours* of various kinds, *cancer*, and *hydatids* have also been found in these membranes on rare occasions.

180. *B. Morbid or effused fluids* are usually contained in the more external sac formed by the arachnoid membrane; but sometimes, as in the brain, between the arachnoid and pia mater; occasionally also between the dura mater and the bony parietes of the canal. Admitting that a limpid serum naturally exists between the spinal membranes, yet an inordinate, as well as a morbid effusion, is not infrequent, particularly in tetanus, epilepsy, some fevers and eruptive diseases, paraplegia, epilepsy, chorea, &c. The more morbid effusions between the membranes are, that of *air*, (Ollivier, Briere, Otto, &c.); large *collections of water*, dropsy of the spine, *hydrorrhachis*, either in an acute or chronic form: it may take place alone, or in conjunction with dropsy within the head: when great it usually produces universal palsy, owing to its pressure on the cord: *puriform matter*, proceeding from ulceration of the spinal marrow, or of its membranes, as in bedridden persons; or from the cavity of the skull (Denmark, Otto); or from carious vertebræ, as well also as effused from abscesses in the vicinity (Brodie, Velpeau, Jackson, &c.); *albuminous lymph*, or a *coagulable* and *organizable matter*, exuded by inflammation of the membranes, or by metastasis of rheumatism to them, as observed also in paraplegia, general paralysis, and in some cases of chorea (Copland and Prichard); and *lastly*, a *bloody fluid* or *pure blood*, liquid or coagulated, arising from injuries of the spine, from concussions of the trunk, from the breaking of an aneurism of an adjoining vessel, as of the aorta, or spontaneously from disease of the spinal vessels, or from some internal cause (Howship, Ollivier, Chevalier, &c.).

181. ii. Morbid states of the Spinal Marrow.—*a.* The *size* and *form* of the spinal cord vary materially. They generally correspond with the length and form of the spinal column: the cord may be too long or too short, in proportion to the rest of the body. Sometimes it is congenitally *thinner* or smaller, either in parts or throughout, especially in monsters with deficient or distorted heads and limbs. But it is subject to a morbid diminution of size—a true *atrophy*, as in *tabes dorsalis* — dorsal consumption. In this latter case, it is sometimes wasted more in one place than in another, being apparently indented and knotty. Atrophy is most frequently met with in extreme old age — *atrophia medullæ senilis*; in protracted cases paraplegia and general palsy; and in the lumbar region of the cord as a consequence of loss of the generative power, and of spermatorrhœa. It often extends upwards along the cord. It may also arise from the effusion of lymph between the membranes—of this association I have met with several instances—in chronic spinal meningitis consequent upon rheumatism, and in connection with chorea. In some cases the diminution of volume is associated with a dirty whiteness and toughness of the fibrous columns, and with a rusty-brown or fawn tint of the grey substance. In other instances, the cord is not only thus discoloured, but also infiltrated with serum, soft and withered (Rokitansky).

182. The cord may be more or less *thin* in parts, from *compression* by the adjoining bones, or by invasion of the canal, by thickening of the intervertebral substances, by bony concretions, by varicose states of the spinal vessels, by aneurisms of the vertebral arteries, by effused blood or other fluids, by hydatide, or by tubercles, or by cancerous or other tumours. The pressure of either of these may be such as almost to divide the cord, or to reduce the pressed part to extreme thinness.

183. The cord may be unnaturally *long* in newborn infants. Béclard found it to descend to the tail-bones in two children born with tails. Extreme *thickness* at certain parts is only congenital; but a portion of the chord may be morbidly swollen, owing to either extreme congestion, or effusion of blood (apoplexy of the cord), or of pus, or of other fluids, in its substance. The *form* of the spinal marrow is most commonly affected by *dropsy* or *hydrorhachis*, also called cleft spine, or *spina bifida*, when connected with an open state of the vertebral canal. This is naturally a congenital malady, associated with cleft of the spinal canal, and often also with internal dropsy of the head, hemicephaly, and hydrencephalocele. It generally terminates fatally with paralysis. But cases have occurred of children living many years with the disease, and even reaching puberty. Paletta and Acrel met with it at seventeen years of age; Henderson at eighteen; Apinus, Warner, and Hochstetter, at twenty; and Camper at twenty-eight. I saw a case of it, with immense tumour in the loins, in a female of about twenty. In rare instances, dropsy of the spinal cord has occurred after birth, and even in adults. This change, in connection with the state of the spinal marrow, is more fully described in the article Dropsy (see *Dropsy of the Spinal Cord*, § 178.).

184. *b. A rupture* or rather *protrusion* of the spinal marrow may occur from *hydrorrhachis*, so that, being itself expanded by the water, or compressed between the membranes by this fluid, it may be more or less protruded through the cleft in the spine, thus forming a *rupture of the spinal marrow* (*hernia medullæ spinalis*). In very rare cases, the chord may deviate from its natural position, in consequence of caries of its bony walls (Ferro, Lecat, Phillip, and Richter). The *colour* of the spinal chord may vary, as that of the brain, but very seldom without change of structure, excepting in some rare instances of jaundice.

185. *c.* The *consistence* of the marrow is more liable to vary. It may be *simply softened*, without

further change, or it may be softened with change, of its intimate structure, forming the *pulpy degeneration* described above (§ 160.), and when treating of the BRAIN (§§ 71. *et seq.*). Its structure may be even entirely broken down : it may be almost liquid or diffluent, or this state may present a mixture of blood. The broken-down state, either with or without blood being effused or infiltrated in the part, may exist only in spots, or in a considerable portion of the cord, and is to be ascribed to diseases which destroy its cohesion, especially inflammation, suppuration, watery infiltration of the substance of the part, and to a morbid or deficient state of its nutrition. Paraplegia more or less complete, or paralysis more or less general, is the usual result of softening; and pulpy degeneration of the cord.

186. *d.* On the other hand, the structure of the cord may be *too firm*, or even *hard.* This state is sometimes conjoined with diminution of size or atrophy in dorsal consumption, and with thickening after chronic inflammation. PORTAL, BERGAMESCHI, EQUIROL, BIRCH, VELPEAU, and OLLIVIER, have found different portions of the spinal marrow nearly as hard as cartilage, particularly in epileptic, insane, and paraplegic persons. GENDRIN has observed the same cord very hard in one part, and very soft in others.

187. *e.* The *continuity* of the structure of the cord may be destroyed by disease, as by extreme pulpy degeneration, by the *laceration* occasioned by the effusion of pus or of blood, and by concussion of the spine. This lesion is, however, more commonly occasioned by wounds, violent extension, fractures and dislocations of the vertebræ. In some of those cases, the marrow protrudes through the opening in the pia mater. Small wounds of the cord may, in some cases, heal.

188. *f. Inflammation of the substance of the cord.—Myelitis* (§§ 154.) is, in some instances, an idopathic disease, and in others, it results from external injuries and diseases of the surrounding structures. Inflammation is to be distinguished from congestion of this part, both in respect of their characteristic appearances, and of their usual consequences. Inflammation may appear in the slightest form of *vascular irritation*, unaccompanied by any very marked change of structure, as in many fevers, eruptive diseases, rabies, epilepsy, convulsions, trismus, tetanus, painters' colic, chorea, in all which the spinal marrow may be more or less affected. This organ may be more unequivocally inflamed either primarily or idiopathically, or consecutively and contingently, especially in the course of some cases of the above diseases. When truly *inflamed — myelitis* — the substance of the cord exhibits a rose-red colour, with some deeper-coloured or dusky spots and streaks, with enlargement of its minute vessels, and injection of the pia mater surrounding the part. In some cases, there is a distinct swelling, and generally some change from the natural consistence, namely, softening, or complete disorganization, or dissolution into a semi-fluid, discoloured by, or mixed with blood. In rarer cases, the inflammatory appearances are accompanied with hardening. Myelitis seldom terminates in *true suppuration.* In rare instances, small abscesses have been found in the cord. *Gangrene* is still more rare. *Ossific deposits*, or *bony concretions*, which are sometimes found in the membranes (§ 179.), do not seem to form in, or even to invade the structure of the cord.

189. *g. Congestion* of blood in the spinal cord may be consequent upon, or conjoined with a varicose state of the veins, or with congestion of the venous sinuses of the vertebral column ; and the congestion when extreme, and especially when connected with atheromatous or fatty degeneration of the vessels (see art. ARTERIES § 59., *and my work on Palsy and Apoplexy*, pp. 266. 288.), many terminate in *effusion of blood* in the substance of the cord, or between the membranes, or external to the dura mater, and between it and the walls of the canal (ABERCROMBIE), owing either to rupture of the diseased vessels, or to sanguineous exudations from them, produced by certain obvious causes, or occurring spontaneously, and without any assignable cause — *apoplexy of the spinal cord.*

190. *h. Hæmorrhage into, or from, the spinal cord*, according to the seat of the vessels whence it proceeds, may exist between the pia mater and the arachnoid — in the internal sac of the arachnoid ; and, when thus seated, there being no laceration of the structure of the cord, it may be inferred that the blood has proceeded from the vessels of the pia mater. In most cases of hæmorrhage into the substance of the cord, the effusion has taken place in the grey substance, and has even been infiltrated to a great extent along the internal canal of its axis (CRUVEILHIER, *Anat. pathol. Leivr.* 3d). Circumscribed extravasations are also found in the structure of the chord, the blood effused undergoing the same changes as described in cerebral apoplexy, and the surrounding nervous tissue also presenting similar alterations (HUTIN, STROUD, GAULTIER, GRISOLLE, BENNETT, &c.).

191. iii. APOPLEXY OF THE SPINAL CORD. — *Hæmorrhage may take place into the external sac of the arachnoid—between the dura mater and arachnoid ; or into the internal sac of the arachnoid, or between the pia mater and arachnoid.* When thus seated, the hæmorrhagic effusion has been called *Hæmatorachis* by OLLIVIER. *When the hæmorrhage occurs into the structure of the cord*, it has been termed *Hæmatomyélie* by this writer.

192. *A.* The *causes of spinal apoplexy* are chiefly injuries sustained on the spine, especially blows, falls, fractures, concussions, &c. Spontaneous hæmorrhage in either of the situations just specified, or *between the dura mater and the walls of the vertebral canal*, is rarely met with ; and when observed, is to be attributed chiefly to pre-existing disease of the vessels (§ 186.); extreme exertion or efforts of any kind, or unusual demands made upon the circulation of the cord, or whatever interrupts the return of blood from or through the vertebral sinuses, being the more immediate or exciting causes.

193. *B.* The *symptoms* of spinal apoplexy have been imperfectly observed, owing to the rarity of the disease, and to the early progress of it having passed unobserved by competent persons. The mode of attack necessarily varies with the seat and amount of effusion. The most frequent phenomena characterising the attack are, pain, sudden and acute, in the region of the spine corresponding with the seat of extravasation, convulsions and paralysis. Precursory shivering and pain are sometimes ex-

perienced shortly before the complete or severe seizure. M. **Calmeil** adduces several cases to prove that, when the hæmorrhage takes place between the membranes, the pain is always acute, and is attended by convulsions or spasmodic contractions, paralysis being slight, or absent, unless the hæmorrhage is very considerable; and that, when paralysis of motion, or of motion and sensation, is sudden and more or less complete, convulsions being slight or absent, the spinal cord is then itself the seat of extravasation. When the hæmorrhage occurs in the cervical region, or in the upper part of the dorsal region, then priapism is generally present, as commonly also observed when these parts of the cord are injured by dislocations or fractures. Constipation and retention of urine are observed at first, and these may be followed, if the disease be not quickly fatal, by loss of power over the sphincters; these symptoms, however, depending much upon the seat and amount of hæmorrhage. When the effusion occurs in the higher regions of the cord, paralysis of the muscles of respiration soon supervenes, owing either to the amount of effusion, and in this case, death quickly supervenes, or to the changes consequent upon the effusion, and then this issue is longer in occurring. The changes may extend upwards, even when the hæmorrhage is low in the spine, and cause death by paralysis of the respiratory muscles, and asphyxia. The following case, recorded by Mr. **Curling**, will illustrate the symptoms and appearances after death of this malady :—

194. A gentleman, aged forty-four, a stout man, of active habits, but a free liver, and subject to gout, had just got into bed about 11 p.m., when he was suddenly seized with spasms in the stomach, and found that he had lost all sensation and power of motion in the lower half of the body. An hour after this seizure, the patient was found shivering in bed by Mr. **Curling**, with complete paraplegia of the whole of the body below the third ribs, and strong priapism. He had perfect use of the arms, but complained of pain about the wrists. No excito-motary actions were producible. His mind was quite clear. After the circulation was restored, the treatment consisted chiefly of cupping between the shoulders, a blister at the nape of the neck, purgatives to unload the bowels, frequent doses of calomel, and regular relief of the bladder. The priapism subsided in about twenty-four hours. There was no extension of the paralysis, except numbness in the hands, and at last imperfect power of using them. During the first eighteen hours after the attack, scarcely any urine was secreted, and it subsequently continued scanty in amount. The breathing gradually became embarrassed and difficult, and the patient died the fourth day after the seizure, his intellect being unaffected until within a few hours of his death.

195. On examination after death, the muscles of the back were much loaded with blood. No fluid escaped on opening the theca vertebralis, the head being in a depending position. The vessels on the surface of the cord were very congested. An incision was made along the front of the medulla, commencing at the part corresponding to the third cervical vertebra, and terminating at the last dorsal. There were two small clots of blood, amounting together to about a drachm, in the interior of the medulla, occupying about an inch and a half in extent, and situated between the origins of the second and third pairs of dorsal nerves. The substance of the cord around the clots was somewhat soft. The medulla was more or less infiltrated, and stained with blood from the site of the clots, upwards as high as the third cervical vertebra, and downwards as low as the last dorsal. (*Third Report of the Proceedings of the Pathological Society of London*, p. 28.)

196. *C.* The *diagnosis* of the lesion, when marked, is not very difficult. The suddenness and severity of the pain, of the spasms, or of the paralysis, and the degree of constitutional or vital shock which ushers it, distinguish it from other spinal affections, and prevent it from being mistaken for rheumatism, with which slighter and more gradual attacks may be confounded. The priapism, where the upper portion of the cord is the seat, and the states of the excretory functions, further aid the diagnosis.

197. *D.* The *prognosis* is always most unfavourable when the attack is such as to admit of a confident diagnosis. But the issue may be protracted, especially when the lower portion of the cord is the seat of hæmorrhage, and is then to be ascribed chiefly to consecutive changes, which may require an indefinite period to produce their ultimate effects. When the effusion is near the pons or medulla oblongata, or even when it is in the cervical region, and especially if it is of considerable amount, at any part of the upper regions of the cord, then death may occur immediately, or in a few hours, or in less decided cases, in a few days. M. **Hutin** found in the cervical portion of the cord two clots of blood. The person died during the night. When the hæmorrhage is very limited, restoration of the lesion, and even of the functions depending upon the seat of lesion, may take place. M. **Cruveilhier** states, that a medical student lived five years after a circumscribed hæmorrhage in the left side of the cervical portion of the cord. Loss of motion was experienced in the same side — in both the lower and upper left extremity. The patient died of a much greater hæmorrhage than the first, and the seat of that was found cicatrized, the blood having been absorbed, and the movements of the side gradually restored. This case shows, that hæmorrhage into the substance of the cord and the seat of hæmorrhage undergo similar changes to those observed in the nervous structures contained within the cranium — that apoplexy of the cord may be recovered from; remains of old apoplectic cysts, similar to those observed in the brain, having been met with in the substance of the cord, particularly in its cineritious structure.

198. *E. The treatment* of spinal apoplexy must be founded more upon the analogy of this disease with cerebral apoplexy than upon the results of experience. It may be directed with the following intentions:— 1st, to arrest, or to prevent a recurrence of the effusion; 2nd, to favour the absorption of the extravasated blood; and 3rd, to keep within due bounds the vascular reaction or irritation accompanying or following upon the process of reparation in the seat of injury. For these purposes, bloodletting, chiefly by cupping-glasses applied on the spine, according to the pulse and habit of body of the patient; terebinthinate epithems or embrocations along the spine; the

facial or lateral recumbent posture, perfect rest; attention to the secretions and excretions; frequent recourse to the catheter, if it should be at all required, and the earliest and utmost endeavours to prevent bed-sores, by recourse to air-pillows, the hydrostatic bed, &c., comprise the chief means that will be found useful in these seizures. Most other measures will either prove inefficacious or injurious, excepting such other means as have been advised for *myelitis* (§§ 171. *et seq.*), which may supervene upon the more limited or slight attacks of hæmorrhage.

199. iv. Tumours of various kinds, developed in, or near to the Spinal Cord, produce effects which terminate fatally, after having occasioned, for an indefinite period, paraplegia or general paralysis. The tumours, or morbid productions, or growths, which may implicate the cord or its membranes, are of various kinds; they may be formed either in the vicinity of the theca, or in the membranes, or even in the cord itself. Certain of these are developed exteriorly to the cord only, and others may even be primarily formed in it, although very rarely, as well as in its membranes, or in its vicinity. *Aneurisms* of the aorta may produce ulceration and absorption of the bodies of the vertebræ, and ultimately affect the membranes, or even the spinal marrow itself. *Hydatids* may produce similar effects.

200. *a. Cartilaginous productions* may invade the vertebral canal, or *exostoses* may form within the canal, diminish its calibre, and press upon the cord. In a case recorded by Mr. A. Key, the ligaments covering the intervertebral substance between the second and third lumbar vertebræ, were hardened and prominent, projecting so far into the canal as to diminish it by one third of its diameter. The patient had lost the power of motion, but retained sensation of the lower extremities. In another case of loss of power of motion, numbness and tingling from the loins downwards, retention of urine, and imperfect command over the sphincter ani, were experienced, terminating in sloughing of the nates and death. "The intervertebral substance above the 12th dorsal vertebra, with the ligament covering it, presented a slight ridge, projecting into the medullary canal, as if an ossification from the edge of one bone tended to unite with a similar growth from the other edge. This transverse ridge manifestly narrowed the canal."

201. *b. Tumours*, fibrous, fungoid, or otherwise organised, malignant or non-malignant, may grow exteriorly to the vertebral canal, and may invade not merely the walls of the canal, but also the membranes and cord itself; or such tumours may commence in, or be attached to, the dura mater of the chord. *Tubercles* and melanoid and other *cancerous growths* are very rarely found in the spnal cord, although not infrequently seen in the brain. *Tubercle* occurs only in connection with tubercles in other organs, and chiefly in the cervical and lumbar regions of the cord, where it occupies the white fibrous structure, and sometimes the grey substance. As in the brain, so in the spinal cord, it occasions red or inflammatory softening, or yellow softening of the surrounding tissue. In some cases, several tubercles, not exceeding the size of millet or hemp seeds, are grouped together. In others, only one tubercle of the size of a pea or bean is found.

202. *c. Cancerous formations* are very rarely found in the cord, and even then chiefly in a secondary form, or in connection with similar productions in other parts. The very extensive experience of Rokitansky, furnished him with only one instance of true and primary cancer of the cord. But he has met with several instances of circumscribed callous induration of the white columns, of the cancerous nature of which he is in doubt. Ollivier mentions several examples of diffused carcinomatous growths implicating the spinal cord, as well as of so-called colloid cancer.

203. *d.* The *symptoms* produced by morbid growths and alterations of structure in the spinal cord and its membranes, or by tumours developed in the vicinity, are generally those which indicate a slowly increased pressure on the cord, or a slowly advancing interruption of the functions of this organ. They are rarely such as enable us to distinguish the nature or the particular kind of lesion producing the interruption, unless a tumour of sufficient size be formed in the vicinity, and even then the information is only partial. As in cases of *softening*, *induration*, or *atrophy* of portions, or of a considerable extent of the cord, the lesions now being considered produce phenomena which vary much with the region in which they are seated, with the nature and extent of the lesion, and with various concurrent or consecutive changes. When the organic lesion is seated in the lumbar region, and is only slightly developed, so as neither to compress nor destroy part of the organ, there are numbness or pain, prickings, twitchings, insensibility, and difficulty of motion of the lower extremities, or even of one lower extremity only. In proportion as the disease compresses or destroys both sides of any portion of the cord, hemi-paraplegia increases and extends, and complete paraplegia is developed. At last, after a longer or shorter time, according to the nature and progress of the lesion, paraplegia becomes more complete, there being loss of motion, sometimes of feeling also, of the lower limbs. Micturition and defæcation, at first difficult, become almost impossible. The catheter is constantly required, as well as the most active purgatives, which are often without effect, inflaming merely the bowels. The patient thus drags on a miserable existence, till at length escars form in the parts subject to pressure, and infiltration of the extremities and loose cellular tissue, and various consequent affections, chiefly suppression of the excretions and absorption of morbid matters, supervene, and terminate life by contaminating the circulation.

204. When the structural lesion is seated in the dorsal region of the cord or of its membranes, or spine itself, the above phenomena are often attended by difficult respiration, owing to impeded action of the inspiratory muscles from impaired influence of the intercostal nerves. And when the cervical portion of the cord is affected, besides the preceding lesions of function, the superior extremities, and even the voice and speech and muscles of deglutition, slightly participate in the paralytic disorder. The whole train of symptoms is often attended at first by little pain in the parts of the spine affected, unless when the lesion is cancerous. These formations are generally developed, more or less slowly, without any symptoms of vascular reaction or febrile commotion;

but contractions of, or spasms, or pains in, the limbs, and severe pains in corresponding regions of the trunk with the seat of disease, are very generally experienced during the more advanced stages.[*]

205. *e.* But little can be said respecting the *diagnosis* of the above lesions with any truth or precision. It has been supposed that scirrhus, or cancer, involving the cord or its membranes, will be indicated by lancinating pains occurring at intervals, especially towards the close of the disease; by a straw yellow tint of the skin; by the presence of the same disease in other parts of the body, and by the advanced age of the patient, as it seldom appears until after the meridian of life. But, although these indications are generally observed, they are not always present. Tubercles can be inferred to be the cause of the symptoms characteristic of organic lesions of the spinal cord, only when their existence in other organs or parts have been or are manifested; and when the early age of the patient, the scrofulous taint, and the absence of inflammatory symptoms further aid this inference. The syphilitic cachexia, and the existence of osseous tumours, externally may suggest the presence of similar tumours in the

---

[*] The following cases, more or less abridged from the original reports, will illustrate the history of the lesions now considered:—

i. *Fibrous tumour in the Theca Vertebralis.*—A female, aged thirty-five, felt pain the back and side, and was very sensible of cold in her legs; the left foot and ankle soon afterwards becoming weak, cold, heavy, with impaired power of locomotion. Two months afterwards the right leg was similarly affected; these sensations, with numbness now extending up to her loins. Her gait was unsteady, but there was no tenderness along any part of the spine. Five months after the first symptoms, she had darting pains in the knees, aching in the loins, and great difficulty in walking. Sensation was impaired. She had cramps in her legs. In about twelve months, she could not stand, involuntary movements of the lower extremities occurred, and she voided urine with difficulty. Fourteen months from the commencement of disorder, sensation and motion of the lower limbs were abolished, but the urinary bladder expelled its contents. Four years from the invasion, any attempt to move caused cramps of her whole frame. She had severe pain in the back and lower part of the body. Both limbs were very cold, and the right was much swollen. Five years from the date of disorder, no sensation or motion existed below the loins, but tickling the soles of the feet produced involuntary movements. She lived upwards of seven years from the invasion of the paralysis.

On *inspection* after death, the body was much emaciated, extensive sloughing existing over the sacrum and hips. The brain was healthy. "At the lower dorsal portion of the spinal cord, there was a tumour, involving the substance of the cord, about the size of the last joint of a man's forefinger. It was of firm consistence, and osseous where it sprung from within the dura mater, opposite the eleventh dorsal vertebra, to the depth of a quarter of an inch, and fibrous, with rough granular matter intermixed in the rest of its structure. Its distinct round form compressed, and was firmly attached to the arachnoid and spinal cord itself, so as to cut into and flatten the nervous substance of the cord. For about two inches below the tumour the cord was much softened, and a little behind its centre was a canal, half an inch long, within its neurine." (Smith and Ewen, *in Reports of Pathol. Soc. of Lond.* 1847 and 1848, p. 180.)

ii. *Tubercles in the Spinal Marrow.*—A laundress, in a delicate state of health for some time previously, complained of pains in the back and lower extremities, with impaired power in her legs. After some weeks, she complained of tingling and pricking pains, and a fortnight afterwards, she had complete paraplegia, both sensation and motion being simultaneously destroyed. She now began to suffer severely from spasmodic contraction of the muscles, chiefly when about to fall asleep, or when the legs were touched or shifted in bed. The knees were then rigidly bent and drawn up to the abdomen. The introduction of the catheter into the bladder, produced the spasms. The bowels were constipated; but after the action of medicine, she could not retain the fæces. She had catching pains, with spasms in the lower ribs and hypogastrium, and pain in the lumbar region, with slight projection of one of the spinous processes. A slough formed on the sacrum; bronchitis supervened, and she died, about three months from the invasion of paralysis.

The *examination, post mortem,* displayed the membranes of the spinal cord in a healthy state; "but at two points, the upper one opposite to the eighth, and the lower to the twelfth, dorsal vertebra the spinal marrow was slightly swollen into a globular form, and felt hard; the surface, in colour, texture, and vascularity, remaining unchanged. On making a longitudinal section of the upper swelling, an oval mass of tubercular matter, three-quarters of an inch in length, and about the same diameter as the spinal marrow, of the firmness of a lymphatic gland, of uniform structure, and of a pale green hue, was seen to occupy the whole interior of the organ, and was invested all round by a thin layer of medullary matter. The structure of the spinal marrow immediately adjoining the morbid growth appeared sound. The swelling a few inches lower down was caused by a similar circumscribed mass of tubercular matter, contained in the interior of the cord, but it was smaller in size. In the left crus cerebelli, close to the pons Varollii, and about its middle, another tubercular tumour, in colour and size not unlike the kernel of a hazel-nut, was found imbedded in the substance of the crus, at the depth of a quarter of an inch from the surface, the adjacent medullary matter being quite healthy. There was also a tumour of the same structure, and of the size of a pea, in the left hippocampus minor. Tubercles were scattered through both lungs, &c." (Mr. Shaw, *in Ibid.*, 1848 and 1849, p. 24.)

iii. *Cancerous tumour in the Spinal Canal.*—A man, aged forty-six, of intemperate habits, could not sit erect without support. There was complete loss of voluntary power below the pelvis, and total anæsthesia in the right leg. He could feel pinching in the left. Reflex action was slowly produced by severe pinching, which easily excited erythema. There was tenderness over all the lower dorsal vertebræ. The paralysis afterwards invaded successively the abdominal muscles and the bladder and arms, so that for some weeks before death, loss of sensation and voluntary motion was complete below the chest. Slight reflex action of the legs could be produced by severe pinching. Convulsive attacks preceded death.

On *examination*, the body was much emaciated. "The brain and membranes were healthy. Within the spinal canal, closely adherent to the theca externally, there existed an irregular encephaloid mass, mottled with dark spots, extending from the third to the sixth dorsal vertebræ, the bodies of which were carious, and infiltrated with cancerous matter. The tumour extended outwards between the spines of the vertebræ and muscles to near the integuments. The portion of the cord beneath it was flattened, soft, and wasted. An ounce of fluid was contained beneath the arachnoid below the tumours." Cancerous matter was found also in the lungs, liver, heart, and pancreas. (Dr. C. J. B. Williams, *in Ibid.*, 1846 and 1847, p. 43.)

iv. *A fibro-carcinomatous tumour invading the Spinal Canal, &c.*—A young lady had a tumour firmly attached between the angle of the eighth rib, and the spinous processes of the vertebræ on the left side. It was hard, painless, and immovable, and of the size of a large orange. Five months afterwards, she had weakness and numbness of the legs, so that she could not stand. On the following day she was completely paraplegic; and on the day after this she passed her motions involuntarily and there was retention of urine. She afterwards had cough, rigors, profuse perspiration, shortness of breath, and quick pulse. She had a slight convulsive fit, and soon afterwards expired — four days from the appearance of paralysis.

After death, this tumour was found to be composed of carcinoma fibrosum, and was very dense. The arches of the dorsal vertebræ and the spines were next raised, and upon the visceral surface of the fourth and fifth, a growth somewhat similar to the external one, and of such a size as to contract considerably the calibre of the vertebral canal, was discovered. "This growth resembled carcinoma, although somewhat lobulated. Opposite to this, the theca was congested, although its normal contour was preserved. Upon opening the theca posteriorly, in the centre, the veins on the posterior surface of the cord were turgid, and the cord itself was a little flattened. When the anterior portion of the theca was divided in the centre, and reflected laterally, the anterior columns seemed to fall spontaneously on either side, and to expose the grey matter of the medulla, which was of a darker tint than usual, and very soft. This softening extended about an inch." The left thoracic cavity was invaded by a tumour corresponding with that in the dorsal region outside. (Mr. A. Key, *in Ibid.*, 1848 and 1849, p. 25.)

spinal canal; but of this there is rarely any evidence; a supposition only can be entertained.

206. *f.* The *prognosis* in the above states of disease is always unfavourable. No correct idea even can be formed as to the term of their duration. After the paraplegic symptoms, or spasms, which they produce, have appeared, a few days only may be the term of existence; or life may be prolonged for several years, as in the cases which I have here adduced. When the lesion is seated in the upper regions of the cord or its its membranes, the duration of the disease is generally much shorter than when it is seated in the lumbar region.

207. *g.* The *treatment* of the structural changes just considered, cannot be directed with much advantage, even if the nature of these changes were sufficiently manifest; but in most cases we proceed in the dark, although in some instances, more or less light breaks upon our path. Yet, whatever may be the particular lesion in this quarter that we may be required to combat, there is one indication which should always guide our steps, and this is to support the vital resistance to the extension of disease. There are very few organic changes which are not increased by inflammatory action, on the one hand, and by debility—by impaired constitutional power, on the other. We should, therefore, endeavour to improve the general health, by promoting the digestive, the assimilating, and the excreting functions, and by removal to a dry, pure, and temperate air; avoiding excitement, and all sources of physical and mental irritation. It may sometimes be requisite to support the strength; and for this purpose such medicines as have the effect may be given with those which are most likely to procure the absorption of morbid growths, or to arrest their progress. With these intentions, the bitter infusions may be given with small doses of the iodide of potassium and the solution of potash, or the carbonates of potash, or Brandish's alkaline solution; and to these the preparations of sarza may be added; or, as circumstances may suggest, the iodide of iron may be given in the syrup of sarza. In many cases, the chief manifestation of disease—the paralysis produced by the organic change, will either be treated empirically or removed from the care of the scientific physician; and, although certain of the means thus employed may be more or less beneficial, especially electricity, galvanism, and electro-magnetism, yet they may be injurious, in some cases, when prescribed without due discrimination. Whenever the paralytic symptoms are attended by spasms or spastic contractions, then these are hazardous means; and the same may be stated respecting nux-vomica, strychnine, and phosphorus. But it is unnecessary to add to what I have advanced above (§§ 173. *et seq.*), or to what has been adduced respecting the *treatment of* PARALYSIS.

SPLEEN — DISEASES OF THE.

— Synon. —Σπλήν, Gr. — *Splen*; *Lien*, Lat.— *Rate*, Fr. —*Milz*, Ger.—*Milza*, Ital.—*Milt.*

1. The *diseases of the spleen* have not attached to themselves that degree of importance to which their not infrequent severity, their prevalence in malarious localities, more especially in warm climates and in armies, and the danger often attending them, most undeniably entitle them. This may be partly owing to the uncertainty hitherto existing respecting the functions of this organ in health, and of the exact nature and pathological relations of the maladies to which it is subject. The superficial manner in which disorders of the spleen have hitherto been considered is an opprobrium, with which not English medical literature merely, but the medical literature of other countries also, is justly chargeable. When it is considered, that our expeditions and armies during the last two hundred years, and in all latitudes, from Heligoland, Walcheren, &c., to Burma and China in the East, and the Monte Video in the West,—that all our colonists and settlers, from Canada to Australia,—that all our dependencies in both the Eastern and Western hemispheres,—and that all races, both fair and dark, more especially the former, have suffered more or less, and have not infrequently been carried off by diseases of the spleen, the imperfect knowledge and scanty literature of these diseases are matters of no small surprise.

2. I. Intimate Structure of the Spleen :—Before proceeding to consider the diseases of the spleen, it will be advisable to offer some remarks upon the normal structure of this organ. From the time of Winslow to that of Andral, this viscus was said to be composed of the following constituents : — 1st, A fibrous structure forming its sub-peritoneal, proper, and investing capsule or membrane, and detaching from its internal surface a number of fibrous septa and filaments, which divide and subdivide so as to form a number of cells into which the blood is effused ; 2nd, Veins, which throughout their whole extent, communicate with these cells by an infinite number of perforations in their sides ; 3rd, Arteries, the small branches of which ramify on the septa of the cells ; 4th, Nerves and lymphatic vessels. Sir E. Home and Beclard appear to have agreed with the foregoing description, and to have viewed the spleen as strictly an erectile structure.

3. More recently the microscopical anatomists, especially of Germany, have upset this account ; and Müller, Ecker, Güsburg, Gluge, Œsterlen, Hessling, Gerluch, Giesker, Arnold, Kölliker, and others, have furnished us with very different descriptions of the structure of this viscus. These, however, by no means agree ; but, as Kölliker's description appears to be the most minute, and to enjoy the most credit—as it is, moreover, published in this country, and in a contemporary work, I shall endeavour to give a brief account of the results of his researches. These are, however, by no means clear, and certainly tend to throw but little light upon the diseases and lesions of the organ.

4. This author notices—1st, The *serous* or *peritoneal membrane*, which accurately covers the outer surface of the spleen, with the exception of the *hilus*, constituting the gastro-splenic ligament, and conveying the vessels to and from the viscus ; this covering is intimately connected with the subjacent fibrous and proper coat of the organ.

5. 2nd, The *fibrous or proper coat* encloses the parenchyma of the spleen on every side, as a sac or envelope, with the exception of the hilus, where the two membranes diverge, and are separated by vessels, nerves, and areolar tissue. The inner surface of the coat "bounds the parenchyma of the organ, and with the exception of very numerous solid processes, which come off from it, is limited by the *trabecular tissue*. At the hilus of the spleen it sinks into the interior of the organ in the shape of tubes (*vaginæ vasorum*), which ensheath the entering and emerging vessels, and are continued on these throughout the whole parenchyma." The fibrous coat is composed of white fibrous tissue, mixed with elastic or yellow fibres ; the former of these consists of bands which take a parallel course, but do not form distinct bundles ; and the latter are united in a very dense and irregular network.

6. 3rd, The *trabecular tissue* consists of "white, shining, flat or cylindrical fibres, which arise in great numbers from the inner surface of the fibrous coat, and in smaller quantity from the exterior surface of the sheaths of the vessels. These are so connected with similar fibres in the interior of the spleen as to form a network which extends throughout the organ. Between the fibres of this net exist a great number of spaces, which are connected with each other, and are occupied by the red spleen substance (5th) and splenic corpuscles (4th) ; and which, although very irregular in respect of their form and size, have yet a considerable resemblance to each other." The trabecular tissue completely corresponds with the fibrous coat, since it consists of white and yellow fibres ; and this Kölliker considers to be muscular ; but, if this be admitted, the fibrous tunic should be considered as muscular also ; and both being viewed us muscular, the contractions of the spleen, so often remarked upon, may be accounted for. Malpighi and others had, previously to this writer, contended for muscular fibres in the partitions of the spleen ; but Kölliker appears to have been the first to demonstrate them microscopically.

7. 4th, The *splenic vesicles or Malpighian corpuscles*, are whitish spherical corpuscles imbedded in the red spleen pulp (5). They are frequently not seen in the bodies of men dead of disease, although normal structures, which are invariably present in the healthy subject. The size of these corpuscles varies from one-tenth to one-third of a line, on an average of one-sixth. They are imbedded in the red spleen substance, and, with the exception of one point, where they are attached to external twigs, they are every where surrounded by this substance. Hessling and Kölliker believe that, in the healthy spleen, they constitute from one-fifth to one-sixth of the whole splenic mass. Each Malpighian corpuscle possesses a special membrane and contents, and therefore is not a solid corpuscle, but rather vesicle ; this membrane appearing to be only a modified portion of the vascular sheaths (§ 5.) with which it is continuous. The contents consist of a small quantity of a clear fluid, and a large quantity of morphous particles, which, according to J. Müller, very much resemble the corpuscles of the spleen-pulp, and have a general likeness to the blood discs, but are irregularly spherical, often resembling the chyle corpuscles. Kölliker maintains that the Malpighian bodies are closed corpuscles, and stand in no connection with the lymphatics ; that they constitute a kind of shut glandular vesicle, and that there is nothing to warrant their being regarded as glandular vesicles.

8. 5th, The *red spleen substance, pulp, or parenchyma of the spleen*, is a soft reddish mass, which fills up all the interstices between the larger partitions and the stronger vessels. Having made a section of the viscus, it is easily scraped off or squeezed out. It consists essentially of three constituents, viz. fine blood-vessels, parenchyma-cells, and small portions of fibres, to which may be added, extravasated blood in various metamorphoses. The cells of the spleen pulp, or parenchyma cells, are similar to the Malpighian corpuscles, but of a darker colour, and of a more variable and smaller size. The blood effused in the spleen pulp and the blood-globules are almost constantly undergoing dissolution in the spleen and disappearing, according to the researches of Kölliker.

9. 6th, The *vessels of the spleen* enter the hilus of the spleen, and on arriving at the viscus, both arterial and venous branches receive, as a covering or sheath, a process of the tunica propria of the spleen, which forms the *vaginæ vasorum*, already noticed (§ 5.). The calibre of the splenic

vein, according to HOME, GIESKER, and others, is in proportion to that of the artery, as five or six to one; whilst the thickness of its coats is very inconsiderable, and it has no valves. The arteries, veins, and nerves are enclosed in sheaths of the tunica propria; and not only are the trunks of entering and emerging vessels thus covered, but their finer ramifications receive a similar clothing. The arterial branches ramify minutely in the Malpighian corpuscles and surrounding red pulpy substance, into which latter part especially, all the fine pencil-shaped ramifications pass; and the commencements of the veins spring from these branches. These nervous commencements or capillaries are tolerably large, anastomose frequently with each other, and scarcely have a special coat as yet. They give the cellular appearance seen in inflation of the veins of the pulp, and which, injected, form structures resembling the corpora cavernosa of the penis. The lymphatics in man are rather less numerous than in the other glandular organs.

10. 7th, The *nerves* of the spleen, proceeding from the splenic plexus, accompany the splenic artery, and divide in such wise at the giving off of its branches, that each artery receives one, or very frequently two nerves which accompany it, and here and there anastomose with each other. The nerves may be traced on the arteries which go to the Malpighian corpuscles; and by the aid of the microscope, they may be seen passing into the pulp, on the pencils of minute arteries.

11. II. THE PHYSIOLOGICAL PATHOLOGY OF THE SPLEEN rests on a knowledge of its structure; and therefore I have endeavoured to give, as succinctly as possible, the results of the researches of KÖLLIKER. HEWSON has remarked, that when an organ receives more blood than it requires for its own nutrition, we may conclude therefrom that the blood undergoes a change from it, or a secretory process takes place; and this applies strictly to the spleen. This physiologist, and subsequently TIEDEMANN and GMELIN, believed that a particular lymph is generated in the spleen, which serves to form blood-globules. But KÖLLIKER opposes this view, and contends that the interior of the spleen is quite poor in lymphatic vessels, and that the blood in the splenic veins is poor in blood-globules; and hence that it is impossible to believe in the formation of a special lymph in the organ, or a relation to the lymphatic system. He contends that no trace whatever of the formation of blood-globules can be detected, but that, at every step of his researches, indications of a dissolution or decomposition of the globules in the spleen were presented to him. He concludes, "*that the blood-globules undergo solution in the spleen, and that their colouring matter is employed in preparing the colouring matter of the bile.*"

12. The contractile power of the spleen was observed by many anatomists, and an explanation of this power has been furnished by KÖLLIKER'S discovery of muscular or contractile fibres in it, as shown above. Hence this viscus can dilate and contract itself by relaxation of its contractile or muscular fibres existing in its balks, coats, and vessel-sheaths; and hence it becomes turgescent, and by contraction of these it becomes small. During its turgescence, a stagnation, and possibly even an extravasation of blood takes place in its capillaries and pulp, the globules thus more readily undergoing solution or destruction; this change taking place in the Malpighian corpuscles, and in the parenchyma cells.

13. This theory of the function of the spleen has received the support of ECKER and BECLARD; and it serves to explain the diseased condition of the viscus, and the influence exerted by those conditions on the œconomy. That this organ is more or less affected in the course of fevers, periodic, continued and exanthematous, is well known, and especially when these maladies assume an adynamic or malignant character. That it is also often disordered or diseased in scurvy, purpura, chlorosis, rheumatism, and in some other chronic maladies, has been remarked; and it is generally admitted, that enlargements and other organic changes of the organ, if they be of considerable continuance, are attended by more or less marked anæmia and emaciation. The emaciation, anæmia, and other changes in the blood, as a superabundance of fibrine, &c., so frequently observed in the progress of periodic fevers, rheumatism, &c., may readily be referred to dissolution of the blood-globules in the spleen during the congestions and enlargements of it in the course of these maladies. J. P. FRANK has remarked respecting the spleen that, "aliorum fere morborum imperio turget et subsidet," and, in these circumstances, the changes produced by it on the blood, cannot fail of being more or less considerable.

14. III. CAUSES OF DISEASES OF THE SPLEEN. — Diseases of this viscus occur at all ages. I have seen them in infants of only a few weeks old, and in very aged persons, as well as at every intermediate age. They are very frequently met with in warm, marshy countries, previously to puberty, in both the white and dark races, but more especially in the children of Europeans born in those countries. The children of English or other European parents born in the East or West Indies, seldom escape some affection or other of the spleen, if they continue to live in malarious districts during the periods of childhood, or until the period of puberty. The male sex is more liable to them than the female, probably owing to the former being more exposed to the causes of splenic disease, and to the greater temperance, and to the periodic discharges of the latter. Of all causes, the *endemic* are the most influential, especially malaria from any of its various sources, and the use of marshy, stagnant, or impure water, or water preserved in tanks, or containing decayed vegetable or animal matters, or both (see art. ENDEMIC INFLUENCE). These causes, according to their concurrence with other causes, or to the constitution of the individual, are productive of either inflammations, congestions, enlargements, or other organic changes of the spleen, generally as a complication or as a consequence of periodic fevers; but they may produce these affections independently of antecedent or attendant periodic fever. Besides these causes, others are not without influence, namely, living in low, humid, and close situations, and in wet, clayey localities, or in cold and damp cellars; debility and vital depression, produced in any way; unwholesome or insufficient food; running, long walks and fatigue; intemperance in food or drink; and whatever contaminates or alters the constitution of the blood and chyle.

15. There are certain circumstances connected with the circulation and the state of the blood, which favours the production of splenic disease, although various local and constitutional causes aid in the result. Continued muscular efforts not merely increase the rapidity of the circulation, but also change, in some degree, the state of the blood itself, and alter more or less its normal distribution in the several organs and parts of the frame. During muscular exertion, the blood is thrown inwards in larger quantity, and distends the visceral veins and large venous trunks, the spleen becoming in some measure a diverticulum to the venous circulation in these circumstances. Somewhat similar changes occur during the cold stage of agues, and in the period of invasion of other fevers, before reaction takes place; but, instead of the circulation being greatly accelerated, and *active* congestion of, or vascular determination to, internal viscera being produced, as in the former circumstances, it is rendered slower than natural in the latter; *passive* congestion of the internal veins and viscera being occasioned by the partial suppression of the circulation in the extremities and on the surface. During the operation of any of the former category of causes, the active determination of blood to the organ may occasion the more acute forms of splenic disease, whilst during the action of either of the latter, engorgements, enlargements, and other chronic affections of the organ are more liable to result.

16. The state of the blood itself also very materially influences the nature and form of the resulting disease. As long as this fluid continues uncontaminated, or preserves its natural crasis, the splenic affection retains more or less of a sthenic character. But when the blood becomes contaminated, either by infectious emanations, or by septic or deleterious effluvia, more especially by such as proceed from the decomposition of animal matter, the spleen experiences the most serious changes, and these generally assume an asthenic or septic character, this organ being not merely congested or enlarged, but also remarkably softened, deprived of vital cohesion, and otherwise greatly altered. There is no part of the frame, which sooner or more remarkably betrays, by these changes, the consequences of vital depression and contamination of the circulation, especially in warm and malarious climates and localities, than the spleen.

17. Amongst the most common causes of disease of the spleen, especially of an acute character, are long marches in malarial countries, running, fatigue; falls, injuries, or blows on the left hypochondrium; drinking cold fluids when the body is overheated and perspiring, unwholesome beverages, and irregularities in diet. Hence the greater frequency of affections of the spleen, and the very acute form which these affections often assume, in soldiers in active service in warm climates. Diseases of a chronic kind, and very often those which are acute, are, in these circumstances, amongst the most difficult and serious maladies which come under the care of the physician; and they are not the less so, that they are seldom primary, and rarely occur in persons previously healthy, they being more frequently complications, or consecutive upon, or sequelæ of other maladies, especially of periodic fevers, of obstructions of the liver, of chlorosis and uterine obstructions, of diseases of the heart and vascular system, particularly the veins.

18. Anxieties of mind, depression of spirits from any cause, discouragements, disappointments, losses of friends or fortune, nostalgia, and whatever tends to lower the tone of the mind, or to depress mental vigour and activity, exert considerable influence both in predisposing to, and in more immediately producing, disorders of the spleen. Persons predisposed by these causes are the most liable to be attacked not only by diseases of the spleen, but even more frequently by those maladies, of which these diseases are either complications or sequelæ; and are much more susceptible of the effects of those endemic causes which are so injurious in hot climates. It is not great heat merely which is productive of diseases of the spleen and their allied maladies, but chiefly sudden falls, or rapid alternations of temperature. At the terminations of the periodic rains, and when the nights become comparatively cool or cold after hot days, the air being loaded with malaria, and the circulation determined, from the surface and extremities, upon the internal viscera, the frequent congestion of the spleen, thereby produced, or otherwise caused, as by the frequent recurrence of the cold stage of an ague, occasions either inflammatory or sub-inflammatory affections, or structural changes of this viscus,—results which the impression of malaria on the nervous system, when aided by mental depression and vicissitudes of temperature, the more certainly and severely induces. In warm climates congestions or other diseases of the spleen seldom occur in females, either primarily or consecutively of periodic fevers, without being associated with disordered menstruation — without delayed menstruation or chlorosis in young females, or suppressed menstruation or leucorrhœa in females of maturer age.

IV. Painful Affection of the Spleen.—

Synon.—*Splenalgia* (σπλην, spleen; and αλγεω, I am pained). — *Dolor lateris, obstructio lienis*, Auct. Var. — *Splenis dolor, — Splenic pain, pain in the left side.*

Classif.—II. Class.—III. Order (*Author in Preface*).

19. Definit.—*Pain in the left side, without febrile symptoms, occurring often suddenly, and frequently ceasing as suddenly, sometimes caused by running, and occasionally being symptomatic of hysteria or uterine disorder.*

20. *A. Splenalgia* most commonly occurs in the circumstances just named, and in its slighter forms it is often complained of by boys or others upon sudden exertion, especially running up hill, or against the wind, or ascending heights; and it usually ceases soon after the causes. When it appears in hysterical females, or in connection with uterine disorder, it is much more obstinate and liable to recur. With the severity of pain referred to the left hypochondrium, there is often either shortness of breath, or a painful stitch on breathing, or frequent sighing, and the pain may be mistaken for pleurodynia, or even for pleurisy; but the absence of febrile symptoms, the circumstances in which it occurs, and its sudden or quick subsidence with the cessation of the cause, sufficiently characterise the disorder, and distinguish it from inflammatory or structural disease of the viscus. When splenalgia is occasioned by running or other

kinds of physical exertion, it may with justice be imputed to a rapid or sudden congestion of the spleen by a greater flow of blood into the organ than return of the fluid by the veins; the sudden distension or turgescence, causing stretching and pain of the fibrous structure and peritoneal envelope of the organ. When the affection is connected with hysteria, or with uterine disorder, or with indigestion, it may be imputed either to sudden congestion, or to a morbid sensibility of the nerves supplying the viscus. It may be remarked, that the term splenalgia has been improperly implied to both inflammatory and organic lesions of the spleen—as a generic term for splenic diseases — by some modern as well as earlier writers: I have restricted it as above.

21. *B.* The *treatment* of splenalgia depends upon its causes. If induced by the nature or amount of exercise, repose will generally soon remove it. If it be neuralgic, or connected with hysteria or uterine disorder, the means advised for these affections respectively will be most appropriate. Whenever this viscus betrays a disposition to disorder, by an increased or morbid sensibility, then a restorative treatment, especially by chalybeate preparations or mineral waters, appears to be indicated. But it should not be overlooked, that this affection, by persistence or recurrence, may pass into prolonged congestion or tumefaction, or into acute or subacute, or chronic inflammation, although this latter is not of very frequent occurrence. In these circumstances, the treatment hereafter to be noticed, should be adopted (§§ 62. *et seq.*).

V. CONGESTION OR SIMPLE TURGESCENCE OF THE SPLEEN.

CLASSIF.—*See Painful Affections of.*

22. *Turgescence* of the spleen is generally *characterised by more or less pain or tenderness, by a fulness or weight, in the left hypochondrium, sometimes by shortness or rather shallowness of breathing, and by various sympathetic feelings, according to its association or complication with periodic fevers or other ailments.*

23. Congestions of the spleen are most commonly met in connection with agues, with obstructions to the portal circulation, and with the other diseases incidental to warm and malarious climates, especially in children and young persons, and the offspring of Europeans in these climates. In its slighter states, congestion of this viscus is often a primary affection, and it then less frequently comes under the observation of the physician. It chiefly, when it occurs as a complication of malarious diseases, or when a frequent recurrence, or a prolonged continuance of congestion, has been followed by inflammation, or by permanent enlargement, or by other organic lesions of the viscus, that this disorder, or rather its consequences, comes under medical treatment.

24. *A.* The *symptoms* of splenic congestion vary much with the extent of congestion, with the rapidity of its occurrence, with the causes which produced it, with the temperament in which it occurs, and with the disorders of which it is a complication. If its accession be sudden or rapid, there is generally more or less pain in the splenic region; if slow, or if the affection be consequent upon ague, pain may not be much complained of. But there is generally a sense of weight or uneasiness, or fulness; and more or less pain or soreness is induced by pressure or percussion of this region, with occasionally manifest enlargement, but more commonly only an indistinct fulness of this part. There is generally no fever, unless the affection be connected with some febrile disease. When the congestion is greater or of longer continuance, the digestive, assimilating, and excreting functions are more or loss disturbed. The fulness or enlargement in the left hypocondrium is greater, is often attended by tension, and the pain or tenderness produced by pressure is more felt. Various sympathetic pains are then often experienced; and the patient presents a more sickly, or a more sallow or lurid, or even a partially anæmied hue. Sometimes, also, especially when the disorder has been of some continuance, emaciation takes place, and the tongue becomes loaded or flabby, or indented at the edges. The skin generally remains cool; the pulse is low or weak, and the conjunctiva pale. The breathing is superficial or short; and the stools are very dark, whilst the urine is pale and of natural quantity. Females are generally during the continuance of congestion of the spleen subject to amenorrhœa, or to difficult and scanty menstruation, or to leucorrhœa.

25. If congestion of the spleen continue long or recur frequently, one or other of the affections about to be noticed generally supervenes, especially in hot and malarious localities, or when the disorder is connected with periodic fevers, or with obstruction to the portal circulation. Prolonged congestion, as well as other chronic diseases of the spleen commonly, is attended by, even if it actually be not influential in producing, a poor or morbid condition of the blood and impaired nutrition. The dark and sallow hue; the pallid lips, tongue, and gums; the general emaciation contrasting often remarkably with the fulness in the splenic region, and the deficient capillary circulation on the surface, impart a striking appearance to persons subject to chronic congestions and structural diseases of the spleen. Whether the changes produced in the blood by the spleen be such as tend to the full elaboration of the blood-globules — to the formations of healthy blood, — as was believed by many pathologists, and only recently denied, or whether the spleen reduces or dissolves the blood-globules, and prevents their excessive formation, as inferred by KÖLLIKER and others, there can be no doubt that diseases of the spleen induce a poor state of the blood, and more or less emaciation. If the former doctrine be entertained, the inference must necessarily be, that the splenic disease impedes the healthy or natural changes produced by the spleen on the blood. If the latter theory be adopted, it will as necessarily follow, that either the diseased spleen does not cease to reduce or dissolve the red globules, or that some other organ or organs take up the office vicariously for the spleen, and that, moreover, this office is discharged to a much greater extent during diseases of the viscus than it is even in health.

26. *B.* The *treatment* of splenic congestion consists chiefly in the removal of, or from, the causes producing the complaint, and in the cure or prevention of the diseases, of which it is consecutive. These causes are chiefly endemic, and hence change of air and locality is essential to a permanent cure of the complaint. Tonics, chalybeates, and stomachic aperients, are generally beneficial. These secretions and excretions should be sufficiently

free; but the means used to fulfil this intention ought not to be of a depressing kind. Stomachic and chologogue aperients should be conjoined with tonics, as the compound decoction of aloes with the compound mixture of iron, &c., or the compound infusion of gentian, with the infusion of rhubarb, &c.; or quinine, or preparations of cinchona may be given in various states of combination, according to the peculiarities of individual cases. In most cases, and even during residence in localities productive of congested spleen, I have found a combination of the sulphates of iron and quina, and the aloes and myrrh pill most serviceable, the last being given in sufficient quantity to act satisfactorily on the bowels. The treatment hereafter to be recommended for chronic enlargements of the spleen, may also be prescribed, in more obstinate cases, or when the disease is complicated with ague or with biliary obstruction. In the former morbid association, the decoction of bark, with serpentaria, or with the nitro-muriatic acids; or the infusion of calumba or quassia with preparations of iron, and sponging the surface of the abdomen with the nitro-muriatic acid solution, and an occasional recourse to a warm bath, followed by frictions with the horse-hair or Indian glove, will generally be most beneficial, due attention being always paid to the states of the intestinal and urinary excretions.

VI. INFLAMMATIONS OF THE SPLEEN.—SYNON. *Splenitis*, Auct Var.—*Lienis Inflammatio*, Sennert. —*Lienitis*, Auct.—*Cauma Splenitis*, Young.—*Empresma Splenitis*, Good.—*Splenite, Inflammation de la Rate*, Fr.—*Entzündung der Milz, Milzentzündung*, Germ.—*Acute and Chronic Splenitis.*

CLASSIF.—III. CLASS.—I. ORDER (*Author in Preface*).

27. DEFIN.—*Pain, increased fulness, weight or oppression in the left hypochondrium and side of the abdomen, with febrile symptoms of a continued, remittent, or intermittent character, according as endemic causes and morbid associations may influence the œconomy.*

28. *Splenitis* is not a frequent disease, especially in an acute, and still more particularly in a sthenically acute form. Much more frequently a sub-inflammatory state, or a sub-acute, or a chronic form of inflammation exists, the last named being often long present before it comes under the notice of the physician, or not being discovered by him until its results have been fully produced, or until they have been disclosed by a post-mortem examination. The existence of acute splenitis has been even denied by some writers; but even independently of the nature of the symptoms during life, the changes found after death, sufficiently indicate an acute form of splenitis.

29. The *causes of splenitis* are those generally which have been noticed as producing indiscriminately the several affections of the spleen (§§ 14. *et seq.*); but there are some which most commonly induce the inflammatory diseases of the viscus. These are chiefly exposure to low ranges of temperature after hot and sultry days in a malarious climate; the suppression of accustomed discharges, as the hæmorrhoids and the catamenia, in these circumstances, especially if the persons thus affected have lived richly, fully, or intemperately. Neglect also of turgescent or congested states of the organ may be followed by inflammatory action, those states being merely the initiatory stages of inflammation. Running, long marches, especially when followed by exposure to malaria, to the night air or dew, or by resting or sleeping on the ground; contusions, blows, or other injuries on the left hypochondrium; and previous functional disorder of the viscus, are frequent causes of the several grades of inflammation of this organ.

30. i. ACUTE SPLENITIS, *when primary or idiopathic*, is most frequently the consequence of severe injuries of the splenic region, or of the spleen itself, and of the extension of inflammatory action from an adjoining viscus, as the stomach, liver, or peritoneum, to the spleen; but it may follow any of the causes already named (§§ 14 *et seq.*).—*A.* It usually is ushered in by chills or rigors, followed by febrile action, and this by perspiration. To these are generally added nausea, depression, a sense of tension and fulness extending from the epigastrium around the left hypochondrium, and sometimes vomiting. A feeling of weight, oppression, and of tension, is soon followed by more or less acute pain, extending often to some distance around the splenic region, and sometimes to the left shoulder; this region being deeply sore, tender, and often somewhat tumid, elastic and tense. There are generally more or less thirst and loss of appetite. The urine is at first clear and highly-coloured, afterwards depositing a sediment. The fever is commonly continued or remittent, with evening exacerbations. At this stage, and with the urinary deposits, or with the occurrence of a copious perspiration, or with looseness of the bowels, or with an uterine or hæmorrhoidal discharge, the symptoms may abate, and the disease subside or disappear; or the inflammation may pass into a chronic state, the symptoms having abated more or less, but the swelling continuing, or being even increased.

31. *B.* In the *most acute* cases, occurring in the most unfavourable circumstances, as in soldiers during long marches in malarious localities, the disease often becomes greatly aggravated when advanced as far as just described, the local symptoms, as well as the general disturbance being much increased. The tongue is furred and dry; diarrhœa supervenes, with sinking of vital power, delirium, hiccup, general tumefaction of the abdomen; or, in other cases, vomiting of blood, black or bloody stools, sunk and lurid features, general agitation and distress, unconscious evacuations, &c., and death in the course of five, eight, ten, or twelve days.

32. *C.* On *examination after death*, the spleen is found increased in size. The peritoneal envelope and proper coat are of a deeper or browner red than usually seen, approaching in places to a black or deep green. They are so soft and friable as to break down easily under the pressure of the finger. The internal structure is still more softened. Some parts appear a little more dense. These present a greyish, or a yellowish grey hue, and contain points of purulent infiltration, which had begun to form, death having occurred, probably from sinking of vital power and contamination of the blood, in conjunction with the local change, before suppuration could proceed. In these cases the disease may be viewed as having gone on to gangrenous softening, or to a state very nearly approaching to this.

33. *D.* In cases less *hyper-acute*, the disease sometimes goes on to *suppuration*, and is generally

of longer duration than the preceding form; but this result of acute splenitis is not frequent, unless in the unfavourable circumstances above alluded to (§ 31.). In these, the disease having apparently reached its acme, in the course of from seven to twelve days, remits somewhat. The febrile symptoms and the pain abate, or the latter changes its character. Chills or rigors occur, terminating in flushes of heat and profuse perspiration. The swelling in the splenic region either increases or becomes more determinate or circumscribed, and the tenderness on pressure continues. The pulse is quick and soft; the symptoms varying much according to the direction the abscess may take. Generally, as the abscess advances, symptoms of partial peritonitis supervene, in the direction in which the abscess proceeds. The peritoneal envelope becomes inflamed at the part where the abscess points, and if adhesions are formed between it and an adjoining viscus, it will break into that viscus; if they be not formed, it will break into the peritoneal cavity, and general peritonitis instantly follow, and soon terminate fatally. Thus, in the course of splenic abscess, the pain in the side may become more acute, and the swelling more prominent, owing to adhesions of the external aspect of the spleen to the abdominal parietes, and to an external pointing of the abscess, which may occur in any situation between the left ribs and ilium, or between the umbilicus and left lumbar region. If the adhesion forms between the spleen and stomach, the gastric symptoms become severe, and the abscess may break into the stomach. Cases have been observed, in which splenic abscesses have thus opened into the colon, into the stomach, through the diaphragm into the pleural cavity, into the lungs, &c.

34. *E. Abscess of the spleen* is generally, but not necessarily, fatal. Some of the cases of recovery, said to have taken place, are not very conclusive; whilst in a very few instances recorded, the evidence of the existence of abscess and of recovery from it is more convincing. Acute splenitis may apparently terminate in suppuration; and the above signs of suppuration (§ 33.) may be present, and even an obscure fluctuation may be detected, and still the existence of abscess of the viscus may be disputed, or these symptoms may be even ascribed to other lesions. From this state the patient may recover; and although we may correctly infer that absorption of the pus formed in the viscus has taken place, yet the proofs of this may not be fully conclusive, although the states of the urinary, the intestinal, and the cutaneous excretions, seem to warrant the inference. When the matter is discharged externally, or even by the stomach or bowels, the patient subsequently recovering, then the fact is conclusive. Dr. Nasse, of Bonn, has recorded the history of a case of splenic abscess, in which the matter made its way from the spleen through the diaphragm into the lung, and was expectorated in great quantity, the patient afterwards recovering. As abscess of the spleen is comparatively rare, such cases must necessarily be much rarer; but there is no reason wherefore abscess in this organ should be less likely, than abscess of the liver, to be recovered from.

35. Rokitansky observes, that, in a favourable case, the abscess may be circumscribed by adhesive inflammation, and, being inclosed in a sac formed by obliterated parenchyma, which has been converted into fibrous tissue, may be borne for a long period; a partial absorption of the pus may take place, and the remainder becoming inspissated, be reduced to a calcareous, greasy pulp, or even to a hard concretion. The more common case is, that the parietes of the abscess also put on inflammatory action and suppurate, in consequence of which the abscess generally enlarges very rapidly, with symptoms of violent reaction in the shape of acute hectic fever. If the inflammation extends to the sheath of the spleen, inflammation of the splenic and adjoining peritonal surface ensues, but is not, however, apt to spread far. He adds, "that the abscess may be discharged into the abdominal cavity, and produce circumscribed peritonitis, which causes the formation of a sac, bounded by the external wall of the abdomen and the diaphragm, the fundus ventriculi, the colon and its mesentery; the entire spleen being thus occasionally destroyed by suppuration." Much more frequently, however, the discharge of the matter into the peritoneal cavity is rapidly followed by general peritonitis and death.

36. Whilst we conclude that acute splenitis may *terminate*—1st, In resolution or recovery; 2nd, In chronic splenitis and various organic changes of the viscus; 3rd, In gangrenous softening or destruction of the organ; 4th, In suppuration or abscess—it may be still further inferred, that splenic abscess may be recovered from—1st, by absorption and diminution of the puriform matter; 2nd, by pointing externally or into some viscus, by which it may be discharged from the frame; but that it much more frequently terminates fatally, by the vital and local changes it occasions, and the contamination of the circulating fluids it produces, or by the consecutive changes it causes in adjoining organs or parts, into which it may proceed or break, as the peritoneum, stomach, &c.

37. *F. Asthenic acute, or consecutive splenitis.*—Acute splenitis is much more frequently a *consecutive* than a primary disease — *consecutive of*, or *complicated with*, adynamic fevers, but more especially, and more frequently and severely with the the jungle, or remittent, or continued fevers of warm or malarious climates. In these circumstances and associations, the severity or malignancy of the fever often masks the splenic complication. The affection of the spleen, if it may be called inflammatory, is of a most *asthenic* and disorganising kind; it implicates all the tissues of the organ, but attacks chiefly its internal structures, and proceeds in a very few days, often in three or four, to produce not only great turgescence, but a complete softening, often amounting to a liquefaction of the viscus. This form of disease is a frequent complication of the periodic fevers — intermittent and remittent — and of the continued fevers of the swampy or jungle districts of the East, and of Africa; and is often also observed in the course of these fevers in the countries bounding the Mediterranean. The *symptoms* of this form of splenitis are not severe, although the changes are most rapid and disorganising, — results which are chiefly to be ascribed to the primary fever, of which the splenitis is a dangerous complication. The ex-

tremely lurid state of the countenance and general surface, the vital depression, the swelling and tenderness in the splenic region, the decubitus on the back or right side, are amongst the earliest and chief signs, those which follow, especially the dry, dark tongue, the vomiting, often with discharges of blood, hiccup, delirium, rapid and weak pulse, &c., being ascribable as much to the primary fever as to this complication, but truly to both. The rapidly disorganising course of this form of splenitis is caused chiefly by the marked depression of vital power, and the condition of the circulating fluids, the spleen being one of the most early parts of the œconomy to experience the effects of vital depression and of vascular contamination, the existence of these states both aggravating and accelerating the unfavourable result.

38. ii. Chronic Splenitis is much more frequently observed than the acute.—*A.* It may occur *primarily*, or *consecutively* of the *acute* or *sub-acute;* for, between the most acute and most chronic or mild, there may exist, as in other inflammatory diseases, every grade of severity or duration. Chronic splenitis frequently does not come before the physician until it has given rise to changes, which, although no longer entitled to the appellation of splenitis, are generally the results of inflammatory action or irritation. In malarious countries, chronic splenitis is most commonly a complication of agues, or a consequence of intermittents and remittents. In these circumstances, the initiatory inflammatory action is often masked by the primary disease. When the chronic affection is consequent upon an acute attack, the passage of the latter into the former is often gradual or insensible.

39. Chronic splenitis, whether primary or consequent upon periodic fever, or dysentery, or hepatitis, &c., may, by muscular exertion, by prolonged or quick marches, by mental excitement, or by injury, or even by a too rough examination of the splenic region, be aggravated to such a pitch as to assume a truly acute or a subacute form. But in many complicated cases, in which the patient has died subsequently to attacks of these diseases, especially in miasmatous districts, chronic splenitis has not been detected, or has been merely suspected, until a post-mortem inspection has shown purulent formations in the substance of the viscus, cartilaginous or ossific deposits in its fibrous coat, false membranes, or adhesions between the peritoneal envelope and adjoining viscera, and other changes sufficiently indicative of inflammatory action, which, however, had either not been manifested during life, or had been overlooked, especially when masked by the primary disease.

40. *B.* The *symptoms* of chronic splenitis are, however, in some cases, more distinctly evinced. The pain, weight and uneasiness in the left hypochondrium are more felt, especially after exertion, and in soldiers after marches. There is generally a remittent or intermittent form of fever, either connected with ague, especially its more irregular types, or simulating this complaint, the exacerbations being most remarkable in the evening or night; the skin being dry, and the pulse frequent, whilst the countenance is sallow, and the skin harsh. As the disease proceeds, the already existing swelling of the splenic region, or even of the whole abdomen increases, or becomes more tense, whilst the extremities and other parts are more or less emaciated. There are always indigestion, disturbed dreams, and obtuse pain or uneasiness in the left side, which is increased when turning in bed, or on pressure. In some cases, a dry cough supervenes, with frequent and superficial respiration, and in others palpitation; and, in the more prolonged or neglected, or improperly treated cases, ascites is superadded. After an indefinite time, either recovery takes place slowly, owing to change of climate and regimen, or death occurs from sinking of the vital powers in connection with changes in this viscus and adjoining parts, especially purulent collections and alteration of the circulating fluids.

41. As in acute, so in chronic splenitis, the variation in the severity and character of the symptoms is very great. The duration also of the latter form varies remarkably. In the course of it various complications not infrequently appear, chiefly owing to the altered state of the circulating fluid, in some cases, doubtless, produced by the absorption of matter from the spleen, or from the extension of functional or structural disease from this viscus to adjoining organs. In many cases, as the disease advances, debility and emaciation become extreme; and hectic fever, sometimes slight, in other instances severe, is generally present. Vomiting or diarrhœa often occurs, and is generally obstinate or attended by discharges of blood either upwards or downwards. Aching of the back and limbs, restlessness, anxiety, weight, soreness, oppression and tenderness in the splenic region, are severally more or less experienced.

42. When considerable enlargement of the viscus attends chronic splenitis, dry suffocative cough, dyspnœa, hiccup, palpitations, &c., are often complained of; and, in some instances, if the inflammation have extended to the surface of the upper portion of the viscus, the peritoneal lining of the diaphragm becomes implicated, and lymph with adhesions is sometimes formed, these symptoms being much aggravated and occasionally accompanied with several of those which I have shown to characterise *diaphragmitis* (see art. Diaphragm, §§ 2. *et seq.*). In other instances, the disease superinduces effusion of fluid in the peritoneal cavity, an occurrence often observed when chronic splenitis follows, or is associated with obstruction to the portal circulation through the liver, or structural disease of this viscus. Less frequently the disease extends to the left kidney; and, in this case, nephritis supervenes, with more or less disturbance of the urinary functions, and aggravation of the febrile symptoms, generally terminating in delirium, coma and death. In rare instances, phlebitis in some limb or organ takes place, and soon carries off the patient.

43. The variations in the severity, the symptoms, associations, as well as the *duration* of chronic splenitis, are very great. If the disease accompany ague, it may be so slight at first as to escape attention; but it generally becomes more severe and manifest with the recurrence of the aguish paroxysms. If neglected at first, it often becomes a painful, a prolonged, and even a formidable disease, generally continuing several months, and not infrequently lasting for some years, with periods of remission.

44. *C.* The *terminations*, or rather the results of sub-acute and chronic splenitis are — 1st, resolution, which seldom occurs; 2nd, aggravation of the inflammatory action to a sub-acute, or even an acute form; 3rd, suppuration and abscess in the forms already noticed; 4th, softening, induration, ossific deposits, &c.; 5th, enlargement, with various associated changes. Although *gangrene* sometimes follows the hyper-acute, or the asthenically or complicated acute form of the disease, it very rarely or never follows the chronic, unless this latter have become suddenly or severely aggravated by exertion, as by long or quick marches in military service, or by external injuries. These consequences or terminations are also common to the acute form, for this rapidly passes into a sub-acute or chronic state, unless when it is complicated with malignant or adynamic fever, and terminates in fatal disorganization or gangrene.

45. Dr. VOIGHT states, that *splenalgia* (synonymous, according to him, with inflammatory affections of the spleen) rarely goes on to suppuration in Bengal; but, when not fatal, it generally terminates in induration, if not cured in time. The febrile symptoms then disappear, and pain in the left hypochondrium is much diminished, but the tumour remains and becomes hard and distinct. The health improves, and, with the exception of costiveness, a sensation of fulness and weight under the left false ribs, a dry cough, some dyspnœa, and occasionally a slight pain shooting to the scapula, the patient feels pretty well, and may live on for many years in that condition. He is, however, generally predisposed by it to fever, liver complaints, dysentery, dropsy and cholera, and by some one or other of these he is at last carried off.

46. In its more severe states, especially when complicated, splenitis runs its course very rapidly, and it may terminate in death in three weeks or a month. Œdema of the feet and legs, ascites, dysentery, ecchymoses, severe affections of the stomach, singultus, are the general precursors of death in sub-acute cases, whilst diarrhœa and hectic close the scene in the more chronic form. Persons who have once had disease of the spleen are very liable to be attacked by it again.

47. *D.* In *children*, chronic splenitis is not an infrequent disease even in this country, at least according to my experience, during the many years of my being physician to the Infirmary for the Diseases of Children; but it is much more frequent in warm climates, especially among the children of European parents. In them it generally commences with anorexia, restlessness or fretfulness, and often sleeplessness. They gradually lose all desire of play, and become indifferent to surrounding objects. These precursory symptoms may continue some days, or even as long as a fortnight, when the colour of health is more or less lost, and degenerates into a pallid, sallow, or even a leaden hue, and the conjunctiva assumes a pale blueish tint. The skin, especially over the abdomen, is dry and hot, and a greater degree of debility is experienced than the severity or duration of the complaint appears to warrant. The pulse is frequent, especially in the evening, and a remittent or hectic form of fever is commonly present; general uneasiness, headache, slight difficulty of respiration, and occasionally palpitation, and pain in the left shoulder, are also complained of. There is a constant feeling of tenderness and of weight in the left hypochondrium, increased by pressure. When the patient lies on his back, and the fingers are pressed under the false ribs of the left side, a hard tumour is felt, the size being generally less than that usually termed enlarged spleen, or even that called congested spleen. The patient dislikes the erect posture, and lies chiefly on the left side with the knees drawn up, and the trunk curved. The bowels are irregular, generally costive, the evacuations being very dark, greenish, or greenish black. The urine is usually pale and copious. After an indeterminate time, either recovery takes place, or more severe or more complicated disease, and more marked sinking of vital power supervene and terminate existence. In some cases, the emaciation becomes remarkable before dissolution, and in these, as well as in others, ascites has often existed for a considerable time previously to death.

48. iii. DIAGNOSIS OF SPLENITIS.—Inflammation of the spleen may be either overlooked, or be mistaken for some other disorder, especially for peritonitis, pleurisy, nephritis, or even for tumours, enlargements, &c., of the kidney.—*a.* When the symptoms of splenitis are mild, and when the disease appears in the course of remittent, intermittent, or continued fever, then it is often difficult to ascertain the existence of the local affection, and it very frequently is overlooked or undetected, until it has advanced to serious organic change. In all periodic fevers, and more especially in persons who have experienced more than one attack of these fevers, and still more particularly in warm, humid, and malarial localities, a very careful examination should be instituted, in order to determine the existence of splenitis or other affections of this organ.

49. *b.* The diagnostic symptoms vary much with the nature of the affection, and with the part of the organ chiefly attacked. When the upper part is inflamed or engorged it may then press upon the diaphragm, occasioning dyspnœa, oppression in that situation, and even pain, which may be mistaken for pleurodynia or pleurisy. If the diaphragm be pushed upwards by the enlarged spleen, the absence of the respiratory murmur, and the dulness on percussion at the base of the left thoracic cavity may suggest the existence of pleuritic effusion. But the absence of aigophony and the extension of the dulness below the margins of the ribs, and the persistence of dulness on percussion in different positions of the body, will indicate the nature of the disease.

50. *c.* The character of the pulse, and of the pain, will generally distinguish splenitis from *peritonitis*; but when the peritonitis is limited to a portion of the peritoneum in the vicinity of the spleen, and the symptoms are not very acute, it is very difficult to distinguish it from splenitis. The peculiarities of the case, the causes of the complaint, &c., will often aid the diagnosis. In *nephritis*, the history and antecedents of the disease, the state of the urine, and the symptoms characterising it, sufficiently distinguish it from affections of the spleen. The same remarks apply to *psoitis*, which can hardly be confounded with splenitis. There is a much greater probability of *tumours* of the omentum, especially when they appear near the situation of

the spleen, being mistaken for chronic inflammation or enlargement of this organ.

51. *d.* Simple *turgescence*, or various grades of *congestion* and *enlargement of the spleen*, may occasion, owing to the stretching or distension of the peritoneal envelope and fibrous coat of the viscus, more or less pain, and may thus be viewed as inflammation of the viscus, and suggest a practice not always the most appropriate to the state of the case. The circumstances and history of the case, especially the state of the pulse and the presence of febrile symptoms, will generally evince the nature of the disease; but it should not be overlooked that the effect of the distension or swelling of the organ upon its envelopes may be such as will often pass into inflammation, if not arrested by judicious means. *Splenalgia* (§ 19.), whether produced by sudden turgescence of the viscus or hysteria, or neuralgia, or uterine disorder, may be similiarly misunderstood, if the causes and alliances of the disorder be not attentively considered.

52. *e.* The diagnosis of *suppuration* or abscess of the spleen is very often difficult, the indications of this change being generally obscure. The antecedent disorder, an irregular recurrence of chills or rigors, the continuance of the febrile symptoms, the softness of the pulse, and the occurrence of sweats of unusual abundance, on frequent occasions, are indications of suppuration, but not actual proofs of its existence. When, however, there is also swelling or tumour in the splenic region, with pain or throbbing, and marked disorder of the stomach, the probability of abscess is greater than when the foregoing symptoms are not attended by any increase of the size of the organ.

53. *f.* The *complications* of affections of the spleen may either render more difficult, or may facilitate, the diagnosis of these affections. Antecedent periodic fevers often indicate the spleen as the organ affected, when other signs of splenic disorder are present; but much more frequently the complications mask this disorder, and render the diagnosis more difficult, especially affections of the stomach, enlargements of the liver, diseases of the heart, pleurisy and pleuritic effusions, peritonitis, partial or general, and dropsical effusions into the peritoneal cavity. When chronic obstructions of the liver, or congestions, or even inaction of this organ, are evinced, or when organic disease of the heart is present, changes in the spleen are very frequently also present, although they may not be manifested during life.

54. iv. The PROGNOSIS of splenitis and other diseases of the spleen depend much upon their severity, their nature, their causes, and their complications. When the affection is simple congestion, and is consequent upon intermittent fevers, the result is much more likely to be favourable than when it appears under other circumstances, or is produced by, or occurs in the course of remittent fever of a low adynamic or putro-adynamic character. When the symptoms indicating splenic disease are obscure, of long continuance, and not amenable to treatment, the risk is much greater than when they are more acute and more deserving of reliance. When the most acute states of splenitis occur, especially when it is detected in the course of adynamic or malignant, remittent or other fevers, the danger should be considered as great; but the degree of danger or the hopes of recovery should depend very much upon the constitutional symptoms, and the states of vital power and of the circulating fluids. The effects of treatment, also, when this is rational and appropriate, ought not to be left out of view.

55. Even when the disease is sub-acute or chronic, our opinion of the result ought to depend much upon the history of the case, upon its origin, upon the state of constitutional power, upon the morbid associations it presents, and upon the evidence of the existence or non-existence of suppuration, or of the extension of disease to the peritoneum or adjoining organs. The signs of suppuration are always unfavourable, although recovery occurs in a few cases where this change has undoubtedly taken place. All the complications of diseased spleen are dangerous, especially pleuritic or peritonitic inflammations, or effusions, organic disease of the heart, obstructions, enlargements, or other structural lesions of the liver, disease of the stomach or bowels, and scurvy. Vomiting of blood, or the presence of blood in the stools, has been supposed by some to be a favourable crisis of splenic inflammations or enlargements. This may be the case in a few instances, but not in others. The occurrence of the catamenia in abundance at the natural period, and of the hæmorrhoidal discharge, is much more favourable than hæmorrhagic discharges from the digestive canal.

56. The prognosis in all diseases of the spleen should be guided also by the severity of the local symptoms, in connection with the constitutional powers of the patient—by the state of emaciation, by the presence or absence of anæmia, by the manner in which the digestive and depurating functions are performed, by the extent of swelling and tenderness in the region of the spleen, by the duration of the complaint, and by the persistence or the removal of the causes, occasional or endemic, from which the disorder arose. As long as the patient continues to remain in the locality concerned in producing splenic disease, either a cure will be rendered difficult or abortive, or the disease will return with the season and circumstances which had previously produced it, with equal or even greater severity, and will either become more complicated, or terminate most unfavourably.

57. The *children* of European parents, residing in warm and malarious climates, affected with chronic splenitis, or other affections of this viscus, seldom recover completely or permanently, unless change of climate or locality be obtained for them. An amendment often takes place during the healthy season; but the complaint generally returns with or after the rainy season, either with increased severity, or in some one of the several complicated forms, in which affections of the spleen present themselves in those climates, death generally, although at some remote period, taking place, often preceded by dropsy or great disorder of the digestive canal.

58. v. TREATMENT OF SPLENITIS.—*A. The treatment of acute splenitis* has been very rationally stated by VAN SWIETEN and SAUVAGES; but at the end of the last century and the commencement of this, the indiscriminate and often improper use of calomel, and of calomel conjoined with opium, superseded a more appropriate practice, especially

in India, and was more frequently prejudicial than beneficial. More recently, the means usually employed have been both more rational and more salutary, although more discrimination in the employment of remedies against this disease, than is usually evinced, is still required. Calomel, or calomel and opium, general and local bleeding, &c., are still too generally prescribed, although, in some cases, either or even all of these may be required. The treatment mainly depends upon the stage or progress of the disease, upon the degree of either sthenic or asthenic action evinced by the local and constitutional symptoms, upon the type or character of the primary or of the symptomatic fever, and upon the air in which the patient resides. These should be severally weighed in connection with the age and constitution, and previous disorders of the patient.

59. *a.* If the attack be recent, acute, more or less sthenic, and the disease be primary, and the symptomatic fever continued, a general bloodletting may be prescribed according to the strength and age of the patient; and this will be the more required if the disease have been occasioned by injuries or causes directly affecting the spleen. In these circumstances, also, calomel, or calomel and opium, followed by a brisk cathartic, will be of service. A second general bloodletting will seldom be required, but local depletions may be necessary. In this form of disease, active purging, and diaphoretics in the intervals, are generally useful. Subsequently the tepid bath, frictions of the surface, and the application of a terebinthinate embrocation, or liniment, as advised in several parts of this work (see Appendix, For. 311.), or a blister over the splenic region, will be of advantage. After the acute symptoms are removed, the persistence of disease in a sub-acute, chronic or mild form, or enlargement of the viscus, will require a repetition of these external means, and a recourse to stomachic and chologogue purgatives, or to such other means advised for these states of the disease, as the circumstances of the case will suggest.

60. *b.* If acute splenitis be consecutive of adynamic, remittent or malignant, or typhoid fever; if it present asthenic characters, even when primary; if the attendant fever be periodic, the pulse quick, weak or soft; if the vital power be very much depressed, although vascular action be excited or the stomach irritable; if the disease has been of some duration, and has arisen from malaria, and its usual consequences; if it have been accompanied with diarrhœa, or by hæmorrhagic discharges; and if the patient still continue, or is likely to remain, under the influence of the air instrumental in causing the attack, bleeding and other lowering means should not be resorted to. A very opposite treatment is required in these circumstances, and should be prescribed promptly and with decision. In these, the sulphate of quinine, the sulphate of iron, camphor, &c., should be conjoined with aloes, a very small quantity of this last acting freely on the bowels when combined with sulphate of quinine. In some cases, it may be necessary to apply some leeches to the left side, and to give a full dose of calomel and camphor at the commencement, and a stomachic purgative in a few hours afterwards, especially if the evacuations betray biliary obstruction or disorder. But, immediately or soon after their action on the bowels, a dose of the following pills ought to be taken; and the embrocation applied over the splenic region, or over the epigastrium, by means of flannel or spongio-piline moistened with it, especially if the stomach be irritable; and this application should be renewed according to the state of the case, and the effects produced by it.

No. 339. ℞. Quinæ Sulphatis, ℈j.; Ferri Sulphatis, gr. xxv; Camphoræ, ℈j.; Extr. Aloes purif. (vel Pil. Aloes cum Myrrhâ) ʒss ad ℈ij; Pulv. Capsici. gr. x.; Extracti Taraxaci, ʒj.; Olei Cajuputi (vel Juniperi), q. s. *m.* Contunde bene et divide Massam in Pilulas xxxvj. Capiat æger duas, bis terve in die.

No. 340. ℞. Linimenti Terebinthinæ, ℥ij.; Linimenti Camphoræ comp. ℥jss.; Olei Olivæ, ℥ss.; Olei Cajuputi, ʒj. *m.* Fiat embrocatio more dicto utenda.

61. The ingredients in these may be varied in quantity, according to the effects produced by them, or others may be added or substituted. If sthenic action or febrile symptoms still continue, the sulphate of iron may be omitted; and if the bowels be already sufficiently acted upon, or if diarrhœa be present, opium may be substituted for the aloes, especially if pain be severe; and the vinum or extractum opii may be added to the embrocation. The warm or tepid bath; diaphoretics, frictions of the surface, and a farinaceous or emollient diet, and gentle aperients, will materially aid these remedies, and remove the disease altogether, or reduce it to a sub-acute or chronic, or mild state. In climates where the patients continue subjected more or less to malaria; in persons addicted to intemperance in eating and drinking, or to the abuse of stimulants or alcoholic liquors; in those who have been subject to periodic fever, or to hepatic or dysenteric affections, acute splenitis often degenerates into the milder forms, or into some one or other of the organic diseases about to be noticed.

62. *B.* If *the sub-acute or chronic form of splenitis* be primary, if it be not a sequela of the acute, or if it do not appear in the course of intermittent or remittent fever, the treatment should depend much upon the severity of the initiatory symptoms. If these be severe, and the pulse excited, local depletion, and a brisk cathartic, will be of service; and if calomel be prescribed at the onset, or suggested by the appearance of the evacuations, it ought to be conjoined with a cathartic extract. I have seen in these cases, as well as in the most acute, a full dose of spirits of turpentine, with an equal quantity of castor oil, taken on the surface of cold coffee, or of milk, or of some aromatic water, and followed by the above medicines (§§ 58—61.), soon arrest the disease, especially when prescribed at an early period. At the commencement of these forms of splenitis, as well as in the acute, the enlargement of the viscus is generally not great, even although the pain may be considerable; but, as the disease continues, and as the more acute symptoms subside, the swelling increases, and the propriety of having recourse to those medicines which support vital resistance, and arrest the progress of the malady, becomes more manifest.

63. When sub-acute or chronic splenitis follows the acute, or occurs in the progress of periodic fevers, then a decided recourse may be had to the sulphate of quinine, combined as above (§ 60.),

never omitting the sulphate of iron, when febrile or inflammatory action is not present; or the infusion or tincture of calumba may be given with the ammonio-chloride of iron, or with the ammonio-citrate of iron, or with the citrate of iron and quinine. Previously to the introduction of quinine into practice, I had employed the decoction of cinchona with ammonia and camphor, and the compound tincture of cinchona, with advantage.

64. In *the consecutive states* of chronic splenitis, the administration of these medicines should not prevent an active recourse to purgatives or cathartics, but these should generally be conjoined with bitters, stomachics or tonics; and the external means, especially the embrocations and liniments already noticed, should not be overlooked. As the disease becomes more decidedly chronic or indolent, the enlargement often increases, and if these means have been duly employed without a satisfactory result, then those about to be recommended for chronic congestion and enlargement of the organ (§ 100. *et seq.*) should be employed, especially the iodide of iron in the syrup of sarza, and the sulphate of quinine and aloes in doses which will act freely on the bowels.

65. *C.* When acute, or sub-acute, or chronic splenitis is followed by symptoms of *suppuration*, or when more precise indications of abscess of the viscus exist, then the indication already stated, viz. to support the vital powers and resistance, should be steadily adhered to, whilst the secretions and excretions ought to be promoted. Various means may be additionally employed, according to the direction which the abscess may take. The most hopeful terminations of this state of disease is to procure the external pointing of the matter, or the absorption of it. The former of these may be attempted by means of poultices, or the insertion of a seton or issue, whilst the powers of the constitution are supported by the means already advised, aided by change of air, and a suitable diet and regimen. The latter, or absorption of the matter, if the internal or constitutional means be not judicious and energetic, may be followed by phlebitis, or by consecutive suppuration or abscess in other parts; but, to obtain absorption when, and as we could wish, is rarely in our power. This end can be attained only by preserving and promoting the digestive and assimilating processes, by promoting the excreting functions, by preserving the bowels in a freely open state, by conjoining vegetable tonics with chalybeates, and by removing the patient to a dry and pure air.

66. *D.* The *complications* of both acute and chronic splenitis should receive due attention.—*a.* If the early stage of the acute or sub-acute disease be primary, and appear to extend to the peritoneal surface of the diaphragm, or pleura, or to the fundus of the stomach, or to adjoining parts of the peritoneum, or to the left kidney, the initiatory bleeding already advised is generally required, and should be in such quantity, or be followed by such an amount of local depletion, as the circumstances of the case will warrant; and calomel, or calomel and opium, in one or two full doses, may also be given. But these should be followed by a cathartic, and preferably by the terebinthinate draught prescribed above (§ 62.), which may be repeated according as it may be required, and by blisters, or the terebinthinate embrocation. Vascular depletion is rarely beneficial in other states of complication, and is generally prejudicial, when the splenic disease appears consecutively, or as a complication of other maladies, especially when it is associated with dysentery, adynamic or remittent fevers, with obstructions to the portal circulation, scurvy, or disease of the heart.

67. *b.* When the *stomach* is prominently affected, and indeed in the other associations of the disease, whether *gastric*, *intestinal*, or *hæmorrhagic*, the terebinthinate embrocations or liniments already prescribed will prove serviceable, if duly persisted in — if applied over the epigastrium, the splenic region, or abdomen, and renewed, as circumstances may suggest. If chronic *diarrhœa* be associated with chronic splenitis, ipecacuanha may be given in the form of pill with the sulphate of iron, quinine, and the extract of hops. If the splenic disease be complicated with *disease of the heart*, our chief reliance should be placed on the sulphate or other preparations of iron, conjoined with the medicines just mentioned, or with henbane, conium, opium, &c., according to the peculiarities of individual cases.

68. *c.* The association of chronic splenitis or its consequences with biliary obstruction, or *hepatic disease*, is very frequent in warm and malarious climates, and is especially obstinate, the splenic affection generally going on to chronic enlargement. In this frequent complication, a weak dilution of the nitro-muriatic acids should be administered both internally and externally—internally with light bitter infusions, as the calumba or cheireita, and the preparations of taraxacum; and externally in foot baths, or as tepid lotions or epithems over the hypochondria and abdomen. The preparations of iron should not be given in this complication. If *jaundice* be superadded, or dropsical effusion into the peritoneal cavity, the supertartrate of potash may be prescribed in large doses, sometimes with small or moderate doses of the potassio-tartrate of iron, and always with extract of taraxacum, in the form of an electuary with any suitable syrup or confection; or the acids already named may be given in the compound decoction of scoparium. Whenever the liver is implicated, the preparations of iron are generally prejudicial, the potassio-tartrate being the only one admissible, and only in small doses. If the associated diseases of the spleen and liver be characterised by enlargement, or if these diseases be very chronic and indolent, the iodide of potassium may be employed, if these acids have failed, and may be conjoined with the solution or sub-carbonate of potash, and the decoction of taraxacum, or the compound decoction of scoparium. In cases such as these, the bowels should be kept freely open, and the constitutional powers duly supported.

69. *d.* For all *hæmorrhages* from the stomach or bowels, in the course of chronic splenitis, the spirits of turpentine, given by the mouth, or even administered in enemata, will be found the most efficacious in arresting the hæmorrhage, when the arrest is indicated as it is most frequently in splenic affections, or when it proceeds beyond what may prove salutary, or when it occurs in delicate, exhausted, or anæmied persons. This medicine may be prescribed, as in the following

formula, the dose being increased or repeated according to the urgency of the attack.

No. 341. ℞. Olei Terebinthinæ, ʒjss. ; tere cum Pulv. Rad. Glycyrrh. ʒjss. dein adde, Mellis et Sy̆rupi Rosæ Gallicæ, āā, ʒjss. et misce. Capiat æger ℥ss. pro re nata.

70. When the consequences of splenitis, especially enlargement or chronic congestion of the spleen, are connected with *amenorrhœa*, or with uterine disorder, the compound iron mixture, conjoined with the compound decoction of aloes is most serviceable.

71. In all forms and complications of chronic splenitis, change of air is extremely beneficial, and the benefit is further promoted when this change is conjoined with a regulated diet and a proper recourse to chalybeate or sulphureous mineral springs, or to artificial waters.

72. *E. The treatment advised by writers* on inflammation of the spleen has been stated more empirically than with due reference to the forms and stages of the disease. The early and acute stage is said, by a recent writer, to require "general bloodletting as long as the inflammatory pain is considerable, provided the patient's strength will admit of it. A moderate degree of catharsis should be kept up. A plentiful application of leeches to the seat of pain, followed by vesication, will sometimes complete the cure ; but the disease is apt to remain latent : it may subside apparently, and then reappear with a violence sooner or later fatal." (*Cyclop. of Pract. Med.* vol. iv. p. 58.) As I have contended above (§ 60.), the most acute splenitis, if it present asthenic characters, will not, however prompt or energetic the depletion may be, admit of this treatment ; and even the most sthenic form of the disease requires the more cautious recourse to depletion, which I have recommended, especially when the disease proceeds from endemic causes. It should be recollected, that the causes are generally of a depressing nature, and if these still continue in action, too free depletion renders the disease more serious, and its consequences more difficult to remove. The re-appearance of the complaint with fatal violence, here said to occur contingently, is frequently owing to the neglect of the tonic remedies which I have advised after the acute symptoms are subdued, especially when splenitis is consequent on periodic fevers, or is otherwise complicated, or when the patient remains in a malarious locality. When, however, the disease is associated with peritonitis or with pleuritis, &c., vascular depletion, general or local, as I have recommended, should not be neglected, with due reference, however, to the peculiarities of the case.

73. Sauvages insisted on the propriety of having recourse to tonics and to chalybeate preparations, in connexion with aperients and sedatives, as soon as the more acute symptoms were subdued. Dr. Bree advised active catharsis, and conium and other sedatives, to remove irritation. He endeavoured to subdue inflammatory action by bloodletting, antimonials and local depletions. Grottanelli, who lived in a country where diseases of the spleen are endemic, advised for simple acute splenitis, and for splenitis complicated with gastritis or peritonitis, or diaphragmitis, or nephritis, or psoitis, hepatitis or peripneumonia, general bloodletting, to be repeated if the circumstances of the case required it, or local bleeding in the nearest situation to the part most affected. As the disease subsided to a chronic state, he recommended those remedies which act chiefly by promoting absorption, and by acting on the kidneys, and which are both antiphlogistic and diluent, as nitre, supertartrate of potash, antimonials, digitalis, &c. If the attack followed suppression of the catamenia or of hæmorrhoids, he prescribed the application of leeches upon the recurrence of painful or severe symptoms, and as soon as all signs of hypersthenia had disappeared, the gradual use of tonics to be followed by chalybeates, especially the ammoniate of iron.

74. Inflammations, as well as other diseases of the spleen, must be treated in great measure with reference to the endemic influences which are chiefly concerned in producing them. In the miasmal districts of Western Africa, and in many countries in the East, these diseases very frequently either are not benefited, or are aggravated by general and sometimes even by local bloodletting, especially in the dark races. In most acute cases, however, local depletions, when duly regulated, are of use. But, in temperate countries, either the one or the other form of depletion, or even both, are more generally required. In those more unfavourable and depressing localities, where greater caution in the use of antiphlogistic means is requisite, and the more acute symptoms rapidly pass into asthenic engorgement and enlargement of the organ, what have recent writers advised ? Before the introduction of quinine into practice, I had occasion to treat cases, in these unfavourable circumstances, and I had recourse, early in the disease, to the decoction of cinchona with camphor, aided by purgatives, and epithems externally, as advised above (§ 60. *et seq.*). Subsequently a much earlier and a much more decided use of quinine, in the course of splenitis, than hitherto advised, was recommended by Nelet, Cruveilhier, Bailly, Piorry, Dalmas, and others, especially when the disease proceeds from malaria, or is associated with periodic fever ; and, even in the early and acute stage, a much more cautious and sparing recourse to vascular depletions and other antiphlogistics, than previously advised, was found advantageous in these circumstances. In most cases, however, purgatives are most serviceable, especially when duly selected, and conjoined with quinine or cinchona, or with preparations of iron, as I have already pointed out (see § 59. *et seq.*).

75. VII. Organic Lesions of the Spleen.—*Structural Changes consequent on Functional and Inflammatory Diseases of the Viscus, and on Periodic Fevers, or other Disorders.*

Classif. — IV. Class, I. Order (*Author*).

76. M. Andral considered that the structural alterations to which this organ is liable should be sought for in one of its two component parts—the part contained, which is blood, and the part containing, which is fibrous tissue. Those affecting the latter, or which are seated in the capsule or its fibrous prolongations, the trabecular tissue and muscular fibres of Kölliker, and in the pulp or parenchyma of the viscus, and in the splenic cells, he thinks, are of comparatively rare occurrence ; those of the former, or which are found in the matter contained in those cells, are more important, inasmuch as they are variously modified, and, he

conceives, intimately connected with the origin and nature of a number of morbid productions. The matter contained in the cells consists of blood and fibrine or lymph. This latter substance was first observed by Hewson, and has been recently viewed by Kölliker, as the fibrinous remains of the blood-globules after dissolution in the intimate structure of the spleen. The importance of this substance in the animal œconomy was insisted on by Tiedemann and Gmelin. M. Andral has made no reference to the observations of these physiologists; but, to the morbid states of this coagulated matter contained in the spleen, he has chiefly ascribed, not only a number of the changes which this organ exhibits, but many also which are found in the other parts of the body. Professors Tiedemann and Gmelin had attributed important offices to this matter, conceiving that it was influential, when carried into the chyle by the absorbents, or into the circulation, in changing the chyle into blood; and they had recourse to pathological facts in support of this opinion. But M. Andral went still further, and conceived that "it enjoys, although not possessed of any distinct organisation, perhaps, a greater sum of vitality than the fibrous tissue which contains it, and consequently is more prone to become altered in its nutrition, and to separate from its own substance various morbid products."

77. M. Andral has erred in imputing to this matter endowments and powers which it is not entitled to, and which are merely changes or modifications of this matter, owing to the states of the vital energies of the frame, especially as manifested in this viscus through the medium of the nerves supplying its bloodvessels and proper tissue, — this matter itself not being the active agent in producing those changes, but the passive recipient merely of the influence exerted on it by the organic nerves supplying the organ, and undergoing changes in consequence of modified states of this influence. Besides, as I have shown above (§ 4. *et seq.*), the views of these pathologists have been disputed in the more recent researches of Kölliker, who has inferred, if he has not fully proved, that the spleen does not discharge the function which they have imputed to this organ, but, on the contrary, a very opposite one, — that it produces a solution of the blood-globules, depriving them of their colouring matter, and preventing the excessive abundance of coloured globules in the blood, which might otherwise occur.

78. i. The Causes of organic lesions of the spleen are, chiefly and more remotely, those already mentioned (§ 14. *et seq.*); but there are others which more immediately and directly induce these lesions, and which consist of previous disease — of one or other of the affections already mentioned, or even of a combination of them—1st, of inflammatory action in some one of its grades, affecting chiefly the fibrous and muscular tissues of the organ; 2nd, of remarkable impairment of vital power and of organic cohesion; 3rd, of morbid states of the blood contained in, or circulating through, the viscus; and 4th, of various combinations of the preceding conditions. During the influence of depressing causes, moral or physical, the spleen often experiences a deficiency of vital contractile power; and it hence soon becomes turgescent, or inflamed if the causes commonly productive of inflammation are in operation, and very soon afterwards engorged and enlarged, or otherwise structurally altered. When the incipient symptoms are inflammatory, this state soon passes into organic change; and it is generally impossible to ascertain during life when the former terminates and the latter begins; the one passing insensibly into the other. With these successive changes, the blood-globules become more and more altered or dissolved, and the fibrine in the blood, or the corpuscles constituting fibrine, more abundant. During the changes of the blood, caused either by agents acting primarily on this fluid, or by disorders of depurating organs, the spleen also early and manifestly undergoes important alterations, for, not only is it more or less congested or enlarged, but its vital cohesion is also remarkably impaired, as shown by its state after death from malignant or adynamic maladies. Many of its organic changes, especially those which are chronic, may be imputed to the frequent occurrence of congestion, or of acute, sub-acute or chronic inflammatory action, or to the absorption of morbid matter, or to the accumulation of injurious elements, owing to impaired excretion.

79. ii. Alterations of the Fibrous Structure of the Spleen. — *A. Lesions of the Capsule of the Viscus.*—These consist — 1st, Of an unusual injection and congestion of its bloodvessels; 2nd, Of softening, in various grades, which may even be so great as to occasion its rupture; 3rd, Of its thickening, either with or without some degree of induration; 4th, Of its transformation into fibro-cartilaginous, cartilaginous, or even osseous substances. These changes are independent of, although very frequently connected with, similar alterations in the peritoneal envelope of the organ, and more especially with inflammatory changes, as effusions of lymph and serum, false membranes on the free surface, or thickening of the peritoneal covering, adhesions to adjoining organs or parts, &c.

80. *B. Alterations of the Trabecular or Fibro-Muscular Tissues and Parietes of the Splenic Cells.* —These are but imperfectly known. This part of the fibrous structure of the organ has been found, however, 1st, in a state of softening; 2nd, in a state of enlargement, rendering the septa thicker and more apparent than natural; 3rd, partially changed, in rare cases, into a cartilaginous or osseous substance. From this it will be perceived, that the changes of the internal fibrous structure of the spleen are nearly the same as those of its capsule. In respect of injection of the vessels ramified to it, and other inflammatory appearances, it may be remarked they cannot be so readily recognised in the internal, as in the external fibrous structure of the viscus.

81. iii. Lesions of the Spleen seated in both its containing and contained parts.— The alterations observed in the coagulated matter contained in the cells of the spleen evidently result from a change in the vital conditions of the organ, by which the internal arrangement of the particles composing this matter is modified. The only question here is, whether this modification takes place subsequently to the formation of this matter, or at the moment of its secretion? Most probably this modification results from the influence exerted by the nerves upon the vessels producing this matter, and is not the remote

consequence of changes experienced by it subsequently.

82. *A. Altered consistence of the spleen* is a very frequent occurrence, and seems to depend upon—1st, the state of its fibrous structure; and 2nd, upon changes in the consistence of the coagulated matter and blood contained in its cells and capillaries. M. Andral refers alterations in its consistence, as well as other lesions of this organ about to be considered, to the state of the blood which fills the splenic cells and capillaries. This is substituting the effect for the cause, although, doubtless, a dissolved state of the blood which the spleen contains will materially diminish its natural firmness. It is much more likely that changes of this kind, as well as the greater number of the lesions of this viscus, depend more upon the state of its organic nervous influence, and upon the vital cohesion of its fibrous structure, than upon the condition of the blood contained in its cells. It may be allowed that the coagulated matter and the blood contained in the spleen experience important changes; but these are surely not primary, but the effects of that influence to which I have now referred them. This view of the subject is supported by the physiological researches of Home, Tiedemann, Gmelin, Schmidt, Prout, and Béclard; and by the experiments of M. Defermon.

83. *a. Softening of the spleen* is a very frequent lesion; particularly in fevers. In this state the natural cohesion of the capsule and of the fibrous and muscular septa is diminished, and the coagulating matter and the blood contained in the cells, pulp, and capillaries of the viscus, have lost their natural crasis, so that they are readily washed out, leaving the fibrous structure entire. In some cases, the blood and the coagulating matter formed in the spleen are quite fluid, and the internal structure of the viscus so weakened and injured, generally from its diminished cohesion and great distension, that an indistinct sense of fluctuation is given upon examining the viscus externally. The spleen, when softened, is seldom diminished in size; it is generally either enlarged, sometimes greatly, or it preserves its natural volume. Softening with enlargement of this viscus is one of the most frequent lesions occasioned by adynamic or malignant fevers.

84. *b. Increased firmness or induration* of the spleen seems to result from augmented cohesion of the fibrous structure of the spleen and blood-vessels, or from a modified state of the coagulating matter contained in the cells of the viscus. In many cases of this description, the blood seems particularly dense, and together with the coagulated matter, gives to the spleen, when divided, the appearance of a slice of the liver. When the increased firmness of the organ amounts to *induration*, the change may be attributed partly to a cartilaginous degeneration of portions of the fibrous structure, to thickening or hypertrophy of this structure consequent upon protracted inflammatory irritation, and partly to the formation of an organised or partially organised lymph, or to a fibrinous deposit in the parenchyma of the viscus. Increased firmness or induration is frequently associated with alterations of size, especially *enlargement*. *Alterations of the size* of the spleen are chiefly referable to the same causes as changes its consistence, viz. to the vital cohesion of its structures, and of the blood and coagulated matte contained in it, and to the action of its differen vessels.

85. iv. Enlargements or Tumours of the Spleen may proceed — 1st, from the diminished cohesion and yielding state of the fibrous substance; 2nd, from diminished action of the veins and lymphatics; 3rd, from a greater quantity of blood being accumulated in the capillaries and cells than is carried out by the veins; and 4th, from a greater quantity of the coagulated matter being formed in, than is removed from, this organ. It is evident that the effect in question seldom proceeds from one only of the above causes, but generally depends, more or less, upon two or even a greater number of them.

86. *A.* When the spleen is much enlarged, it often ascends in the left hypochondrium, thrusts the diaphragm upwards, and, becoming more closely applied to the surface of the ribs, occasions as dull a sound on percussion as is heard in the right hypochondrium from the presence of the liver. Sometimes the enlarged spleen, pressing thus upwards, does not project beneath the margins of the ribs. In this case its enlargement can only be determined by percussion and auscultation. But more commonly it descends below the margins of the left ribs, occasioning a tumour, varying in dimensions and form. This tumour occupies the left hypochondrium, and may be so large as to extend to the left flank, to the epigastrium, and to the umbilical region. In some cases I have seen it so much enlarged as to extend to the right side of the abdomen. It should, however, be recollected that the spleen may form a tumour below the ribs without being materially enlarged, owing to the diaphragm being pressed downwards by an effusion of fluid into the pleural cavity. Instances of excessive enlargement of the spleen, with or without induration or increased firmness, have been recorded by authors. Columbus and Schenck record cases in which the viscus weighed twenty pounds, the fibrous envelope being nearly cartilaginous. Burrowes saw one which weighed twelve pounds, and J. P. Frank one that was sixteen pounds weight. The more chronic cases of enlargement are frequently attended by some degree of induration; whilst the more rapidly formed instances of enlargement, as frequently observed in the more pestilential or miasmal climates, are characterised by more or less softening or friability of the viscus.

87. *B. Chronic tumours or enlargements of the spleen* — vulgarly *ague-cakes* — are very different from the enlargements of the viscus which take place from *vascular congestion* (§ 22. *et seq.*), and which occur not infrequently in the course, or as a sequela of adynamic or exanthematic fevers, or other diseases. These tumours differ in character, and are owing partly to hyperæmia, partly to the deposition of the anomalous fibrous product already noticed in the parenchyma of the spleen. The consistence of the organ varies greatly. The tumour or enlargement is most probably at first soft, but becomes harder, according as the deposit is more coagulable, and as the more fluid parts are absorbed. The colour of the swollen or enlarged viscus is probably at first reddish, but becomes paler as the colouring matter is absorbed, and as increased vascularity yields, and gives place to the fibrous deposit.

88. *C. Diminished volume* of the spleen sometimes occurs, but much less frequently than increase of its size. Occasionally it is very much diminished. M. ANDRAL has seen it no larger than a walnut. In cases of this description, the consistence of its fibrous structure, and of the contents of its cells, may be either increased or diminished. With the causes of atrophy of the spleen, and of the particular circumstances connected with it, we are altogether unacquainted.

89. *D. The colour* of the spleen is occasionally considerably changed. In some cases it is of a bright red, deepening through all the shades to a blackish hue. When this occurs in spots only, the organ presents a speckled appearance. It sometimes also assumes, in certain portions, a whitish or yellowish tint; these portions either retaining the same consistence as the rest of the organ, or being harder or softer than it. It is difficult to say whether this change of colour depends more upon diminished vascularity of the fibrous structure of the part thus affected, or on change of the colour and consistence of the coagulated matter and blood contained in the parenchyma and cells of the viscus. M. ANDRAL imputes it entirely to the latter cause, and thinks it does not result from the formation of any new production.

90. v. MORBID FORMATIONS.—1st, *Purulent matter* is sometimes found in the spleen, either in isolated drops disseminated through its parenchyma, or in abscesses of various dimensions. These latter may here, as in the liver, be separated from the surrounding parts by a false membrane or cyst, or may be in immediate contact with, or pass insensibly into, the sound parts. Abscesses devoid of any cyst sometimes acquire a large size, occupying the greater part of the internal structure of the viscus. In these cases, the surrounding parenchyma is generally soft, pulpy, and readily breaks down notwithstanding the utmost care. In the parts most distant from the collected matter, the capsule and fibrous tissue generally remain unchanged; but when the capsule comes in contact with the purulent matter, it also loses its vital cohesion, and allows the collected matter to find its way through it, either into the peritoneal cavity, or, having formed adhesions to adjoining viscera, into them. Abscesses of the spleen may thus burst into the stomach, the colon, the thorax, and even into the urinary passages. Cases have also been described, wherein they have found their way, externally through either the anterior abdominal parietes, or the back, or even the loins; but such occurrences are extremely rare.

91. Infiltration of purulent matter into the parenchyma of the spleen, as well as its collection in distinct abscesses, may coexist with similar depositions in other parenchymatous organs. Thus pus has been found in the spleen, liver and lungs, and even in the brain also, of the same subject. It is sometimes found in one or more of these organs and in the cavities of the joints in the same case. In all these cases the pus is formed in some other part, as in the veins, in the sinuses and cavity of the uterus, &c., whence it passes into the current of the circulation, and is either deposited in these situations, or occasions an inflammatory state of these parts, rapidly followed by the suppurating process. For reasons assigned in another place (see arts. ABSORPTION, ABSCESS, *symptomatic*, and VEINS, *diseases of*), I believe that the latter more commonly obtains. In some instances, as in phlebitis, metritis, &c., purulent matter is formed in the part primarily affected, and subsequently appears in the spleen only; but more generally it is also found in some other situations at the same time. The majority of instances, in which purulent matter is found in the spleen, are of the above description. Those instances in which the pus has proceeded from inflammation, acute, subacute or chronic, originally affecting the substance of this viscus, are not common, unless as a complication of remittent and intermittent fevers; but in these cases of primary formation of matter in the spleen, according to my experience, a distinct abscess or abscesses are found, and rarely infiltration only, this latter being always a consecutive deposition or formation.

92. 2nd. *Tubercular matter* is not infrequently found in the parenchyma of the spleen, generally in the form of minute grains, either isolated or clustered together. Tubercles of this organ are much more common in children than in adults; but they seldom are found in it, at any age, unless they exist in other organs at the same time. Tubercles are very common in the spleen of the lower animals.

93. 3rd. *Cysts*, of various kinds, are occasionally found in this organ. Their simplest form is that of small vesicles filled with a serous fluid, existing either singly or in clusters. These vesicles are sometimes found in great numbers. M. ANDRAL states, that they are not confined to the splenic cells, he having found them within the splenic veins, some floating loose, others attached by peduncles to the sides of the veins, and others again lodged between their coats. He has also observed cysts of a much more complicated structure in the spleen: these consist of a serous, or sero-fibrous tissue, containing either a honey-like matter, or a substance resembling suet, interspersed with hairs. *Hydatidic* cysts are sometimes found in the spleen, but not so frequently as in the liver. Their mode of development in the former is in every respect the same as in the latter (see art. LIVER, § 232.).

94. As to *the origin* of the above formations much difference of opinion exists. M. ANDRAL supposes that they are nothing else than the blood contained in the splenic cells modified in its qualities. "The experiments of M. GENDRIN," he observes, "seem to prove that the blood may be converted into pus. The result of my own observations has convinced me that, by a simple alteration of its colour and consistence, it may be converted into a substance perfectly analogous to the encephaloid tissue described by LAENNEC. Let us go a little further, and suppose the blood in small circumscribed masses deprived of its colour, and diminished in its consistence, so as to become curdy and friable, and we have then all the essential characters of tubercles." (*Anat. Path.*).

95. The changes which M. ANDRAL supposes to commence in the blood contained in the spleen should rather be referred to an alteration of the coagulated matter or lymph formed by the vessels ramified on the parietes of the splenic cells; both because the morbid deposit is more immediately produced by the vital action of this viscus and of its vessels, and is not a fluid circulating merely

through it, and there arrested in its course; and because the morbid productions to which this author has referred, particularly tubercles and encephaloid tissue, have closer points of similarity to this particular coagulated matter than to the blood itself. Besides, we have no proofs that blood ever undergoes changes, similar to those for which M. Andral contends, from being contained in, or circulating through, the capillaries or cells of an erectile tissue. Whatever changes the splenic blood may undergo, must result either from the state of organic nervous or vital influence, with which the spleen is endowed, or from the condition of the blood circulating in it, or from the properties of the coagulated matter which it is engaged in forming, supposing that this matter mixes with the blood taken up by the splenic veins. These causes may combine to produce the ultimate effect; but the first should be viewed as primarily and chiefly influential, and the latter as early results, inducing further effects.

96. The *proximate causes* of the foregoing lesions of the spleen may depend—1st, upon irritation in various grades up to acute inflammation; such as increased vascularity, induration, ossific change, primary formation of matter, &c.; 2nd, on a diminution of the nervous and vital influence of the organ, affecting the action of its vessels and its functions, and the state of the blood contained in the capillaries of its proper structure and cells—as softening, changes of colour, congestion, enlargement, &c.; 3rd, on obstructed return of blood through the veins, as from organic disease of the liver or of the heart, especially congestion, enlargement, induration, &c.; 4th, on a tendency existing in the system to the formation of the matters found in the spleen — as pus, tubercles, cancerous matter, cysts, &c. This tendency may depend on the local or general states of vital influence; or the substance found in the spleen may be conveyed through the channel of the circulation, and deposited or secreted in this situation. It is possible also that both these may coexist.

97. vi. Hæmorrhage in the Spleen.—*Apoplexy of the spleen*, Cruveilhier. — This able pathologist has described the hæmorrhages sometimes met with in the substance of the spleen, especially in the course of intermittent fevers. Hæmorrhagic deposits of various sizes, rounded in form, and exhibiting all the changes which the blood undergoes in apoplexy of the brain or other organs, are the appearances usually presented in cases of splenic apoplexy. Ochry-brown cicatrices and fibrous cysts of the same colour, observed in rarer instances, may be viewed as the remains of former hæmorrhages, with breach of substance. Hæmorrhagic effusion into the parenchyma of this viscus should not be confounded with pulpy softening of this viscus, from which it is altogether distinct. M. Cruveilhier remarks, that, at every strong muscular effort, the blood rushes into the structure of the spleen, distending it, and thereby causing rupture. What renders this opinion the more probable is the frequency of hæmorrhage in the spleen of the horse. M. Bailly has also adduced cases of spontaneous hæmorrhage into the substance of the spleen from ague.

98. vii. The Diagnosis of organic diseases of the spleen is extremely difficult as regards certain of them, and very easy as respects others. Enlargement and induration of this viscus are readily recognised, unless they be slight or incipient. The existence of *abscess* of the spleen is to be inferred from the history of the case and the symptoms mentioned above—especially when the acute disease has passed the sixteenth day, the viscus increasing in size,—if fever be exasperated towards night, with increased heat in the soles of the feet and palms of the hands, — if rigors appear, followed by flushes, perspirations, and a soft pulse, — and if the complexion become more pallid, leaden, or sallow, and the bowels more relaxed. The existence of the other organic lesions of the spleen is often not manifested during life, and can very rarely be inferred with the least precision, either from the history of the case or from the symptoms complained of. Pulpy softening, however, when accompanied with more or less tumefaction, may be suspected from the softness and tenderness of the swelling and the antecedents of the case, but the examination ought always in such instances to be conducted with gentleness and care; for the spleen may be ruptured during life by a rough examination, especially in the advanced stage of remittent fever, during which this state of the spleen chiefly occurs.

99. viii. The Prognosis of structural changes of the spleen entirely depends upon the nature of these changes, many of which cannot be ascertained during life. The existence of *abscess* is always dangerous, but not always fatal, as recovery may take place in the manner already mentioned. *Enlargements* of the viscus are always serious maladies; but, when they are not excessive, are not associated with obstructed liver or disease of the heart, are not accompanied with a boggy or pulpy feel upon examination, or extreme hardness, they may either be removed, or the patient may live some years without change in the tumour or in his general state. If the enlargement be pulpy or boggy, if it be attended by much tenderness or pain, or by extreme hardness, or accompanied with protracted diarrhœa, or with exhausting hæmorrhages from either the stomach or bowels, or with disease in the liver or other organs, or with abdominal dropsy, the prognosis should be very unfavourable. In all cases of inferred alteration of the spleen, the constitutional symptoms and the complications should guide the prognosis, especially the apparent amount of vital power, of vascular fulness, or of anæmia, and the connection existing between it and diseases of other organs.

100. ix. The Treatment of structural diseases of the spleen has been in great measure stated when noticing the treatment of chronic splenitis. The chief and most common changes of this viscus, which come under the care of the physician, are *enlargement* and *induration*, and these are the usual consequences either of acute, sub-acute or chronitic splenitis, or of repeated attacks of congestion, caused by obstinate agues, especially in miasmal localities. After having recourse to purgatives, in the combinations already mentioned, more especially with sulphate of quina, sulphate of iron, &c. (§ 60. *et seq.*), and to liniments and embrocations applied over the splenic region, these morbid conditions generally disappear; but, if they still continue, the *iodide of potassium* may be prescribed in connection with such other means as

the peculiarities of the case may suggest, as with the compound decoction of aloes, or the compound mixture of iron, or with both; or the iodide of iron may be taken in the syrup of sarza. In those cases frictions of the surface of the body, especially over the hypochondria, with the liniments already mentioned, will prove very beneficial. During the treatment of these chronic and obstinate diseases of the spleen, due attention should be directed to the disorders which are so frequently associated with them, and more especially to obstructions or other affections of the liver, and disorders of the stomach and bowels.

101. In many cases of chronic enlargement or induration of the spleen, especially when associated, as either lesion very frequently is, with chronic disease or torpor of the liver, the *nitro-muriatic acid*, taken in the infusion of chereita or of calumba, with extract of taraxacum, and the external use of this acid, either as a bath to the extremities, or as lotion, wash, or epithem over the hypochondria, will prove most beneficial. If hæmatemesis or discharges of blood from the bowels occur, the state of the case should be duly weighed. If the patient have lived fully or richly, if he be young, plethoric or robust, the hæmorrhage may prove more or less critical, and should not be prematurely arrested. In different circumstances, or when it proceeds too far as respects the condition of the patient, the arrest of it may be generally accomplished almost immediately by the spirits of turpentine, taken either in a full, or in small and frequently repeated doses, as prescribed above (§§ 62. 69.).

102. When amenorrhœa or chlorosis is connected with enlargement of the spleen, the combination of the compound steel mixture with the decoction of aloes, or the aloes and myrrh pill with the compound galbanum pill, may be prescribed and continued for some time, or the other medicines just now recommended may be taken, but due reference should always be had to the history of the case, and its various morbid relations.

103. *Change of air* is the most important means of cure in all chronic affections of the spleen, and more especially when the patient resides in a low, humid or miasmal locality, or in a hot and aguish or sultry district. Change to a more healthy climate, as far as this may be effected, or even a sea voyage, is essentially necessary to a complete or permanent recovery. When change of air can be associated with the use of *chalybeate* and *deobstruent mineral springs*, or artificial mineral waters of this kind, then the advantages of change will be very materially enhanced. Many of the chalybeate, saline chalybeate and sulphureous waters of this country, of Scotland, Germany, &c., will prove very serviceable in completing a cure of splenic disease; but the particular spring which should be adopted ought to depend upon the peculiarities of particular cases.

104. The *diet* and *regimen* of the patient require strict attention, and should be duly regulated. If the patient live in, or have been removed to, a healthy air and locality, an abstemious or moderate and digestible diet, with temperance in the use of vinous or other beverages, will of itself, in due time, effect a cure; but this regimen should generally be only brought in aid of the treatment already advised, adapted with discrimination to the circumstances of each case. Care ought to be taken never to overload the stomach. Farinaceous articles of food should be taken in due proportion, and animal food only once in the day, in moderate quantity. Instead of the usual kinds of flesh meats, the more digestible kinds of fish — white fish — may be substituted twice or thrice in the week; but the fish ought never to be fried. Cocoa should be preferred to tea or coffee. Moderate exercise in the open air and in sunshine ought not to be neglected, more especially when splenic affections are accompanied with anæmia or chlorosis.

STERILITY—See Impotence and Sterility, also, Pollution, Voluntary.

STOMACH, DISEASES OF,—Comprising Cardia and Pylorus.

—Synon.—Stomach, Γαστὴρ, στομαχος;—*Ventriculus, Stomachus*;—*Magen*, Germ.;—*Ventricule, Estomac*, Fr.;—*Stomacho*, Ital.

1. The stomach not only sympathises most intimately with other organs, but also exercises over them a most powerful influence: it is not merely a passive sufferer of disorder on numerous occasions, but is, on many others, itself either actively diseased, or the most influential agent of the disorder of other organs. Hence, in many diseases, even of the most serious kind, the stomach is either chiefly affected, or most intimately sympathises with the organ which is the seat of the disease. (See art. Sympathy.)

2. In most affections of the stomach, and in many diseases with which this organ sympathises, there are certain prominent symptoms which may be—1st, functional, or independent of any appreciable structural change of the organ or of any other part; 2nd, or be caused by inflammatory, or by organic lesion of the viscus; 3rd, or arise from disease of some allied organ or part, or even of the frame generally. These prominent and frequent symptoms are—*flatulence, acidity, heartburn, acrid eructations, water-brash or pyrosis, rumination, gastrodynia, nausea, and vomiting*, &c.; and as several of these may depend upon disorder of other viscera as well as of the stomach, the special consideration of them has been assigned to different heads, chiefly to Morbid Appetite, Flatulence, Indigestion, Digestive Canal, Gastro-enteric Disease, Pyrosis, Rumination, Vomiting, &c.; and to these articles I beg to refer the reader for various topics intimately connected with those involved in the present subject.

3. In our investigations of diseases of the stomach, the organisation, the structural, the nervous, and the vascular connections of the organ, the viscera bounding, and in close contact with it, and the varying states of its fulness and vacuity, should severally receive attention, especially in connection with habits and modes of living, with diet and regimen, with age and sex, and with artificial or injurious modes of dress. These severally, or more or less associated, modify not only the states, but also the position, not of the stomach merely, but also of surrounding viscera. *The functional disorders* of the stomach have been duly discussed under certain of the heads now enumerated, especially *flatulence* and *indigestion*; but before I proceed to consider the inflammatory and structural diseases of the organ, I shall offer a few remarks on the more painful affections usually referred to this organ, and which have generally been termed *gastrodynia* and *gastralgia*.

4. I. Painful Affections of the Stomach.—Synon.—*Gastrodynia* (from γαστὴρ, stomach; and ὀδύνη, pain);—*Gastralgia* (from γαστὴρ, and ἀλγέω, I suffer pain);—*Cardialgia* καρδιαλγια, Sauvages, Darwin, Pinel, &c.;—*Spasmus ventriculi, Cardiaca passio*, Auct.—*Limosis Cardialgia*, Good;—*Morsus ventriculi, dolor ventriculi*, Auct. Var;—*Doleur de l'estomac, Colique d'estomac*, Fr.;—*Magenschmerz, Magenkrampf, Magendrücken*, Germ.;—*Mal di stomaco*, Ital.—*Pain in the stomach; cramp or spasms in the stomach; nervous affection of the stomach.*

Classif.—II. Class, III. Order (*Author in Preface*).

5. Definit.—*Severe, sometimes violent, pain in the region of the stomach, often of sudden occurrence, and, after an indefinite continuance, generally quickly ceasing; frequently eased by pressure, and unattended by tenderness or fever; commonly symptomatic, and very rarely primary, unless produced by injurious ingesta.*

6. The very painful seizures, commonly referred to the region of the stomach, and usually termed *gastrodynia*, or *gastralgia*, or *gastro-enteralgia*, are very generally viewed as affections of the nerves supplying this organ, such affections being often accompanied by more or less spasm of the muscular coats of the viscus. This view is probably correct, although the evidence in its support is by no means demonstrative; for the morbid sensibility constituting the seizure may have its origin either in the nerves distributed to the stomach, or in the ganglia or plexuses, whence these nerves proceed, or in those in the more immediate vicinity, as in the diaphragmatic nerves; or it may even be caused by the irritation and spasm produced by biliary calculi. The existence of spasm of the gastric muscular coats is often doubtful; in some cases the pain presents spasmodic features; in others, it is not thus characterised. That the pain occasionally extends to both stomach and bowels, as inferred by some writers, the affection being in such cases called *gastro-enteralgia*, may be admitted; as it is difficult in all instances to dissociate the affection of the nerves of the stomach from a similar affection of the intestinal nerves, either co-existing or supervening the one on the other. This more extended affection will thus very nearly approach to the severer forms of colic or ileus, especially when the suffering in this latter affection is more or less referred to the epigastrium.

7. *Gastrodynia* occurs under a variety of cir-

cumstances:—1st, it may be altogether nervous or functional, and unconnected with any evidence of inflammatory or structural lesion; 2nd, it may depend upon various grades or kinds of inflammatory action; 3rd, it may proceed from any of the structural lesions about to be considered; and 4th, it may be connected with gout, appearing in the form of atonic, misplaced, or metastatic gout, or even with rheumatism, although very rarely with this latter. It may, moreover, occur sympathetically of various other diseases, especially those which are seated in the abdominal viscera. The first of these manifestations of gastrodynia chiefly interest us at this place. In this state of the disease, as well as in the other, the secretions poured into the stomach are often much disordered, most frequently they are more or less acid. The acidity in these cases is either the cause of the pain, or the consequence, in the first instance, of the functional disorder, of which morbid sensibility constitutes a chief part, the pain being increased by the acid or morbid fluid and gaseous secretions produced during the impaired organic nervous or vital power of the stomach.*

8. This affection may occur in very different or even opposite states of the stomach. It may appear during inanition, or, at least, during an empty state of the viscus, or after repletion or an overloaded condition of the organ. It may be connected with anæmia, or with great vascular fulness. It may be referred to the nature or incongruity of the ingesta, or to flatulent distension; and it may be associated with any of the functional or structural affections of the stomach already noticed (§§ 2, 7.). In its severer forms, gastrodynia is sometimes associated with a morbid appetite or with gout, and in this latter state it often assumes the form of *cardialgia*, — a form which many writers have described as a combination of gastrodynia with leipothymia, the distress being referred equally to the epigastrium and the præcordia. Gastrodynia, in its less violent forms, is often an attendant upon difficult or scanty menstruation, but it still more frequently assumes the form of gastro-enteralgia, or even of colic, in females who experience catamenial or uterine disorder. The more sudden and violent accessions of pains, with the shorter continuance, and more rapid cessation of suffering, has been referred to cramp or spasm of the viscus; but, even admitting this condition to exist in these cases, a neuralgic state of the nerves of the viscus, or of those in the immediate vicinity, owing probably to some temporary irritant, may equally constitute the pathological condition; in either case the one morbid state will hardly exist, with much violence, without the other. Broussais and his followers would not admit the existence of either of these conditions independently of inflammatory action or structural change. This view of the complaint is sufficiently controverted in the article on Gastro-enteric Disease, and in what will appear in the sequel; the most severe states of gastrodynia often appearing under very different circumstances from those of inflammatory action or structural lesion.

9. i. The Causes of gastrodynia are remarkably numerous, and nevertheless it is sometimes difficult to assign the attack to any particular cause. The affection is frequently connected, more or less, with temperament and habit of body—with the nervous, irritable or bilious; and is hence somewhat hereditary. It is much more frequent in the female, than in the male sex, especially during uterine activity, and in the form of spasm or of cramp; in the nervous and susceptible; in persons of sedentary habits; in the insufficiently or unhealthily fed; and in those who are subjected to anxieties of mind and to the depressing emotions. Females are most liable to it about the period of the catamenia, and during gestation; also after large losses of blood, and prolonged leucorrhœa. It is often associated with anæmia, or chlorosis. Gastrodynia, in its severer forms, is one of the most frequent consequences of masturbation, in either sex; of a vegetable, poor and indigestible food; of taking cold and acid beverages or fluids, especially during an over-heated state of the system; or acid and unripe and stale fruits; of living in low, humid, and unwholesome localities; of intemperance in the use of spirituous or vinous liquors; and of the more indigestible or incongruous articles of diet, or of excessive repletion, produced either by food or drink. The causes enumerated under the head of Appetite, Morbid, Flatulence, Indigestion, &c., are equally productive of the affection now being considered.

10. ii. The Symptoms of gastrodynia consist of the character, mode of accession and duration of the pain, and of the associated phenomena. The

---

* The following remarks, pertinent to this subject, have been published by Dr. Bence Jones, who has most ably investigated this and many other topics in animal chemistry.

"In 1785, Carminati first observed the acid reaction of the digestive fluid. Werner, in 1800, confirmed the observation. Prout proved, in 1824, the presence of hydrochloric acid during digestion and in indigestion. Tiedemann and Gmelin found, in 1826, by irritation of the stomach, that acid was secreted; chiefly hydrochloric acid. They found also traces of acetic acid; and in the horse they found also butyric acid. About 1830, Berzelius states that the acid reaction of the contents of the stomach is chiefly from hydrochloric acid; and the acids next in importance are the lactic and butyric. He concluded, from his own experiments, that lactic acid existed in all animal fluids, either free or combined. In 1844, Liebig showed that this conclusion was not correct, — that there was no lactic acid, even in milk, until it began to decompose; and this he showed to be true of other animal fluids. In 1845, I (Dr. Bence Jones) observed that when much acid is secreted by the stomach, the urine is found to be alkaline. The excess of acid in the stomach was hydrochloric acid; and the free alkali in the urine was fixed alkali, and not ammonia. In extreme cases, the alkalescence lasted for four hours. As the free acid was absorbed from the stomach, the urine became acid, and this reaction increased until it was intensely acid to test paper. Thus, then, in health and disease, hydrochloric acid is liberated in the stomach. Acetic acid is sometimes present in small quantities, and perhaps lactic and butyric acids may occasionally be found. Phosphoric acid has not hitherto been proved to exist in the gastric fluid.

"The progress of animal chemistry leads to the expectation that many more organic acids will be found to be present in the stomach in disease. Starch and fat are two of the three great constituents of the food of man, and each gives origin to a long series of organic acids; the last of which in either case is carbonic acid, the product of respiration.

"The varying circumstances of disease render it probable that in disorders of the digestive organs, many of the intermediate acids may be produced; that, although in the state of health the starch passes readily into carbonic acid and water, yet in the state of disease, lactic acid, acetic acid, and formic acid, may be produced. So, also, one or many of the fatty acids will most probably be found to result from indigestion. Thus, butyric, caproic, and caprylic acids, closely related to each other in composition, are not unlikely to be present in the secretions of the stomach in disease." (See Dr. Seymour, *on the Nature and Treatment of several severe Diseases*, &c., vol. i, p. 3.)

pain may be acute, pungent, lacerating, cutting, burning, or obtuse, dull or aching. It may be sudden, rapid, or slow in accession; and after continuing momentarily, or for a very short, or even an indefinite time, cease suddenly, quickly, or slowly. It may remit or intermit, or recur at irregular or indeterminate periods. It may occur at any period of the day or night, especially the former, and in every state of the stomach, more particularly when empty or overloaded. It may be attended by great distress and appearance of suffering; by constant restlessness, agitation, tossing, or even convulsive or spasmodic movements; by extreme anxiety, anguish, palpitations, tumultuous or irregular action of the heart, or by epigastric pulsations; by groaning, moaning, and irregular states of respiration, both diaphragmatic and voluntary; by choking in the throat, eructations of flatus, or partly of flatus and of acid, rancid or even alkaline matters, or the more forcible rejection of nidorous or variously disagreeable fluids. There are frequently borborygmi, flatulent distension at the epigastrium, and often in the other abdominal regions, sometimes with irregular spasmodic contractions, and efforts to vomit, the attempts being either abortive, or partially inefficient. The skin is often cool, especially the extremities, and the sufferings occasion a free or cold perspiration. Pressure of the gastric region generally affords a temporary ease. The countenance is anxious or partially sunk; the tongue is not materially changed from pre-existing states; the appetite may be morbid, ravenous, or lost, with or without nausea or retching. Thirst may or may not be experienced; and the bowels may be costive or irregular, and the stools more or less morbid. The urine may be pale and abundant, especially in females, when the gastrodynia is associated with uterine disorder. The pulse may not be materially affected, or it may be slow, intermittent, or irregular; or it may be small, quick and irregular, whilst the action of the heart is hurried and tumultuous. Retchings or *vomitings* may or may not be present; but when the latter are observed, they are such as are described in that article.

11. iii. DIAGNOSIS. — It is often difficult to determine whether the pain, attended by more or less of the above symptoms, be purely nervous, or the more prominent phenomenon, caused by spasm, or by inflammatory or organic disease of the stomach, or of a closely adjoining part. The history, the concomitants, and the grouping of the symptoms of the case, will chiefly guide the physician. The causes of the attack ought to be carefully investigated before a positive opinion be formed or given. Attention to these: the absence of fever, of tenderness on pressure, or of tension, or of increased heat near the seat of pain; the state of the urine, and of the secretions generally; the free perspiration and coolness of the surface; the character of the pulse, and even of the pain in most instances; the existence of the nervous temperament, or of the hysterical or gouty diathesis; the *juvantia* and *lædentia*, the effects of treatment, the habits, modes of life, the cravings, and the diet of the patient, will severally assist the diagnosis.

12. When the pain is caused chiefly by, or is connected with, *spasm* or *cramp of the stomach*, the morbid action, as Dr. MACFARLANE has shown, in a very excellent paper on this subject, is communicated by the nerves to the muscles, inducing the most acute pain, with a feeling of rigid contraction, violent twisting or tearing in the epigastrium, soon followed by painful or interrupted breathing, difficult articulation, pallid countenance, small, hurried and contracted pulse, and occasionally with coldness of the extremities, and rigid contraction of the recti abdominis and gastrocnemii muscles. Pressure on the gastric regions in these cases, instead of increasing the pain, as in inflammatory and organic diseases of the stomach, generally affords more or less relief in this affection, which in some instances is followed by an attack of hiccup.

13. In all cases of gastrodynia, the nature of the ingesta, not only for a few hours previously to the attack, but also for several days, ought to be ascertained as accurately as possible; for the poisonous, injurious or incongruous nature of these may have occasioned the attack; and, although inflammatory action may be the concomitant of the gastrodynia, this latter may be the chief lesion, the former being either asthenic, or of a kind which should be viewed as altogether subordinate. The nervous character of the complaint is sufficiently manifest in many cases; but in certain circumstances, especially when occurring in the gouty or rheumatic diathesis, or in the form of displaced gout, it is sometimes associated with congestion, or with asthenic inflammatory action; and much greater importance is frequently, in such cases, attached to these latter pathological conditions, than to the state of the organic nervous power and vital resistance, which are too often allowed to sink, or which are even hastened to collapse by lowering or inappropriate means.

14. iv. The PROGNOSIS of gastrodynia is generally favourable when the attack is not attended by tumultuous, or irregular, or intermittent action of the heart, or by leipothymia, or by a sense of fatal sinking, or a presentiment of approaching dissolution. These often accompany misplaced or metastatic gout, or the occurrence of severe gastrodynia in the gouty diathesis, or an attack in a person who is already the subject of organic disease of the heart, and should be viewed as extremely dangerous symptoms, although no indications of inflammations or structural change be present, or may be detected in the stomach or collatitious viscera after death. Several instances of this kind have come before me, one of them in a medical man. If the attack occurs in a person far advanced in life, or addicted to the abuse of spirituous or vinous potations, the existence of organic disease in this organ, or in its collatitious viscera, may be inferred, especially if singultus be present, and a prognosis may be formed accordingly. Nevertheless, the attack may not be the less nervous, this being the most important part of the disease, as respects the existing suffering, and that to which immediate attention should be directed, as respects both the prognosis and the treatment. In the severer form of gastralgia, attended by the symptoms of cramp or spasm of the stomach, a cautious prognosis should be given. In a case published by Dr. MACFARLANE (*Glasgow Med. Journ.* vol. ii. p. 182.), of cramp of this viscus, the coats at one part, were found completely torn asunder, so as to produce a large opening, no appearance of disease having been

detected in the vicinity or in the margins of the aperture.

15. v. Treatment.—The *indications* of cure are —1st, to allay the suffering of the patient; and 2nd, to prevent a return of the attack by ameliorating or removing the morbid conditions occasioning it.—*A.* The *first* of these is often best accomplished by ascertaining and expelling the cause of disorder, more especially when poisonous or injurious ingesta has produced it. In such cases, the treatment should be directed as very fully stated, with reference to the individual *poisons*, at the places where these are considered; for the removal of these, by an emetic, or by mechanical means, as there advised in respect of numerous injurious substances, or the neutralising or counteracting their actions, is most essential to the obtaining of relief, whenever the attack can be traced to these causes. If the attack be attended by vomiting, or by eructations, the state of the matters thrown off should receive attention; and if these furnish indications of acidity, the combination of antacids with emollients and anodynes are required. If the gastrodynia be characterised by cramp or spasms, rather than by acidity, antispasmodics and emollients should be given in frequent or large doses, with opium, camphor, æther, ammonia, &c. The following will generally afford relief:—

No. 342. ℞. Magnesiæ Calcin. ℈ij.; Tinct. Opii ♏xxxvj.; Spirit. Carui ʒii.; Aquæ Flor. Aurantii, Aquæ Pimentæ, āā ℥iijss. Misce. Capiat æger cochl. iij. larga, omni horâ, vel bihorio.

No. 343. ℞. Mist. Amygdal. dulc. ℥vss.; Acidi Hydrocyanici diluti. ʒss.; Tinct. Opii ʒss.; Spirit. Lavand. comp. ʒij. M. Fiat Mist. cujus sumantur cochl. iij. larga, secundis vel tertiis horis.

16. Whilst these or other appropriate medicines, as may be found in the Appendix (see *Form*, No. 357.), are being employed, either of the *embrocations* there prescribed (see *Form*, 311.), may be applied by means of warm flannels or spongiopiline over the epigastrium. When the pain is attended by retching, it is sometimes beneficial to promote vomiting by copious draughts of warm emollient fluids, in order to dilute and promote the discharge of irritating ingesta, or of morbid secretions. After these have been duly evacuated, it is often requisite to allay both the irritability and the morbid sensibility of the organ by giving, along with each dose of either of the above medicines, one of the pills now prescribed.

No. 344. ℞. Creasoti ♏ij.; Pulv. Cretæ comp. ℈ij.; Syrupi Papaveris q. s. M. Fiant Pilulæ xij. capiat unam vel duas, pro dose.

17. When the gastrodynia is accompanied with much flatulence, or assumes a milder and more chronic form, or recurs frequently, the following may be taken, and repeated according to circumstances.

No. 345. ℞. Magnesiæ Calcinatæ (vel Sodæ Carbon.) gr. xij.—xvj; Pulv. Rhei gr. viij.; Pulv. Cascarillæ (vel Pulv. Calumbæ) gr. v.; Pulv. Cinnamom. comp. gr. iij.; Aquæ puræ ℥iss. Misce. Fiat haustus.

No. 346. ℞. Bismuthi Nitratis, et Magnesiæ Carbonatis, āā gr. x. ad xij.; tere cum Mucilag. Acaciæ ʒjss. dein adde, Aquæ Flor. Aurantii ʒij.; Spirit. Anisi ʒj.; Tinct. Hyoscyami ♏xxv.; Aquæ puræ ʒx.; Syrupi Tolutani ʒss. Misce. Fiat Haustus statim sumendus et horas post tres repetendus.

18. If the pain in the stomach be connected with biliary disorder, a full dose of calomel and opium may be given at first—from five to ten grains of calomel, and from one to two of opium; and afterwards magnesia and rhubarb may be given in any aromatic water. If there be reason to infer that hydrochloric acid is present in the stomach, either vomiting should be provoked, or absorbents exhibited previously to the calomel; and if the retention of the latter by the stomach be doubted, a drop of creasote may be given in addition to opium, or morphia. The gastrodynia caused by the retrocession or suppression of gout requires very decided means. I have seen several cases of this kind, and each one was somewhat different from the others in its features, and in the effects produced by treatment. In one case (of a medical man), the attack was associated with enteralgia; in another, it was complicated with marked biliary disorder; in a third, it was attended by great disorder of the urinary organs. For the first magnesia, camphor, opium, and capsicum, were freely given in conjunction; for the second, magnesia, calomel, and opium; and, for the third, the carbonate of soda, with camphor, carbonate of ammonia, and hydrocyanic acid. For all of them, terebinthinate embrocations were directed to the abdomen, and mustard cataplasms to the feet. The results were favourable in all. The treatment should vary with the peculiarities of each case; and these are so many, and often so different, according as the pain is associated with disorder of organs with which the stomach is connected by position or sympathy, that it is impossible to state all the means, or combination of means, which will be quite appropriate to all.

19. *B.* Having removed the present attack, it is requisite to ascertain, as fully as possible, the conditions of the several digestive and excreting functions, and to trace the influence which disorder of any of these may have in favouring a return of this affection. In most cases of gastrodynia, more or less indigestion or weakness of the digestive functions generally, or impaired action of the liver, and disorder of the excreting functions, are present, not merely for a short period, or contingently upon some manifest cause, but in a chronic or protracted form; and for these a well-divised course of treatment is necessary both to remove them and to prevent their recurrence. Biliary accumulations or obstructions should be removed by chologogue purgatives; weakness of the stomach, by bitter infusions, or other tonics; torpor of the liver, by mild mercurials, taraxacum, or the nitro-muriatic acids, according to circumstances; impaired excreting function, by diuretics, diaphoretics, aperients, emmenagogues, warm baths, &c. Acidity of the prima via ought to be prevented by antacids, as the fixed and volatile alkalies, magnesia, chalk, &c., conjoined with tonics or aperients, or even with both. Antispasmodics, carminatives, and anodynes may be added to these, according as indications for their use may appear, with a view of preventing, as well as of removing, an attack of gastrodynia, which may occur in females, especially about the period of the catamenia, or in nervous or irritable persons from errors in diet, although no very manifest disorder of any of the abdominal organs can be detected.

20. There is no disorder for which a duly regulated diet and regimen are more required than for gastrodynia. As to the *diet*, which is found

the best in this complaint, it is most difficult to determine. Articles of food which agree well in some cases, disagree in others. Pure cocoa, black tea in small quantity; farinaceous articles of diet; animal food in moderation, and chiefly mutton or game; and abstinence from saccharine substances, from pastry and from heating beverages, are generally deserving of adoption; but it is unnecessary to add to what is already advanced on this subject, and on *régimen* and the use of *mineral waters*, when treating of INDIGESTION (see § 55. *et seq.*), with which the complaint is so intimately allied, and of which it so frequently forms the most distressing part.

21. II. INFLAMMATIONS OF THE STOMACH. — SYNON. — *Gastritis* (from γαστηρ, the stomach); *Ventriculi Inflammatio*, Boerhaave;—*Febris Stomachica Inflammatoria*, Hoffmann; — *Cardialgia Inflammatoria*, Tralles; — *Gastritis*, Sauvages, Vogel, Cullen, Parr, Pinel, &c.; — *Cauma Gastritis*, Young;—*Empresma Gastritis*, Good; — *Gastrite*, *Inflammation de l'Estomac* Fr.; — *Entzündung des Magens*, *Magenentzündung*, Germ.; — *Inflammazion des Stomaco*, Ital.

CLASSIF. — 1. *Class*, 2. *Order* (Cullen); — 3. *Class*, 2. *Order* (Good); — III. CLASS, I. ORDER (*Author in Preface*).

22. DEFIN. — *Anorexia, nausea, with pain in the region of the stomach, with or without chills or rigors; followed by febrile symptoms, by vomitings soon after the ingestion of substances, by a desire for cold fluids, by increased pain and tenderness on pressure, and, in the severer cases, attended by an internal sense of heat or burning, by extreme anxiety and dejection of mind, and by irrepressible vomitings or retchings.*

23. It is of some moment, upon entering on the consideration of inflammations of the stomach, to keep in recollection the organisation and the connections of the organ, and more especially the intimate structure of its villous coat, the nerves which supply it, which actuate its vital functions, and which forms the bonds of sympathy between it and the brain, spinal cord, and associated viscera; and the relations, functional and structural, between the enveloping serous covering and surrounding viscera, on the one hand, and the internal surface of the other portions of the alimentary canal on the other;—duly to consider the very intimate connection subsisting between this viscus and the chief ganglial centre; the analogy, presented by the digestive canal and vessels proceeding from it, to the roots of plants; and the general type of conformation existing, in respect of this organ, throughout the whole animal creation.

24. Before proceeding to discuss the several forms or states in which gastritis occurs, I shall consider the causes of the disease, as they are chiefly concerned in producing or modifying these states; the morbid effects generally presenting a more or less manifest relation to the causes or concurrence of causes producing them.

25. i. CAUSES OF INFLAMMATIONS OF THE STOMACH.—These are often the same as occasion inflammation of other organs; but there are many causes which most frequently and especially produce one or other of the forms of gastritis.

26. *A.* The *predisposing causes* of gastritis are more especially such as favour the occurrence of inflammation generally; as depression or exhaustion of organic nervous power, functional disorders of the digestive, assimilating and excreting organs; alterations of the circulating fluids, especially imperfect depuration of the blood, and vascular plethora; high ranges of temperature, in connection with a humid or malarious atmosphere; habitual excesses in food and spirituous or vinous liquors; sedentary employments, or occupations which are followed in a stooping position, mental application and the depressing emotions; the suppression of eruptions or accustomed discharges, of periodic losses of blood, or of external painful affections; convalescence from fevers or other acute maladies; sympathy with diseases of other organs or structures; and tight-lacing in females, or close cinctures, &c.

27. *B.* The *occasional exciting causes* are chiefly those which consist — 1st, of injurious ingesta; 2nd, pre-existing disease; and 3rd, mechanical agents or physical influences. — (*a*). Excesses in food or drink, beyond the usual quantity of either, or as regards the incongruous nature of the articles; irritating and indigestible food, especially dried, preserved, or long-kept animal substances; various kinds of fish, more particularly shell-fish, in certain idiosyncrasies; a too high or too low temperature of the articles taken into the stomach, especially when taken in large quantities, and in predisposed states of the frame, unnatural distension and oppletion of the stomach; the excessive use of any stimulant, particularly alcoholic liquors, tinctures, cordials, &c., of aromatics, spices, rich sauces, highly seasoned dishes, &c., or of vinous, saccharine, acid, or fermenting beverages; an inappropriate recourse to irritating emetics or purgatives, particularly in large doses, as when the former has been thus given in order to procure the expulsion of narcotic or other poisons; the ingestion of any of the numerous articles comprised in the classes of irritant, acrid and narcotico-irritant poisons (see art. POISONS); the use of various resinous, oleaginous, alkaline or acid medicines in too large or frequent doses, or of various vegetable or other concentrated principles; spoilt, putrid, or rancid or unwholesome kinds of food, or impure, stagnant, or contaminated water; rancid, fatty, or oleaginous articles; and unripe, acid, or stale vegetables or fruits.

28. (*b.*) Pre-existing disorders or diseases may run on to some form or other of gastritis, either by their increased severity, or by their extension to one or more of the tissues of the stomach. Thus, flatulence and other forms of indigestion, pyrosis, morbid appetite, or rumination, may pass into gastritis, either spontaneously, or more commonly after errors of diet or regimen, or after a recourse to injudicious remedial means, or to unwholesome or unsuitable food or drink. Biliary disorders, particularly accumulations of acrid bile in the gall-bladder or ducts, may occasion gastritis; the irruption of the bile into the duodenum, and partially into the stomach, irritating or inflaming both these viscera. Disease or severe injury of distant organs, with which the stomach is most disposed to sympathise, as the brain, kidneys, uterus, skin, &c., may not only predispose, but even excite this viscus to inflammatory action. More frequently, however, the stomach becomes implicated either by continuity of structure, or by contiguity of position. Thus inflammation of the œsophagus may extend to the stomach, or both

diseases may be co-etaneously induced, as when vomiting has been procured by large quantities of mustard, and of this result I have seen two or three instances. The villous coat of the stomach and small intestines may be effected either more or less extensively, or in a limited extent at first, the inflammation extending afterwards more or less in either direction, according to the predisposition and to the nature of the exciting cause. The stomach not infrequently also becomes implicated in the course of inflammations of the liver, diaphragm, peritoneum, spleen, gall-bladder, &c., chiefly in consequence of contiguity of position. In these cases, inflammatory action of a portion of the peritoneum extends to the opposite part of the peritoneal coat of the stomach, occasioning an exudation of lymph, and adhesion of the opposing surfaces, with more or less disease of this viscus. This succession or extension of inflammation from the surrounding viscera to the stomach, is often observed in warm climates, especially among Europeans who have migrated thither.

29. Gastritis may be induced by powerful mental emotions, or mental shocks; or by the suppression of rheumatism or gout, or of any accustomed discharge; and these diseases may either be a predisposing cause (§ 25.), some exciting cause having occasioned the gastric attack; or they may be the only efficient cause which can be detected, the gastritis even occurring without any circumstance which could account for the suppression or retro-cession of either of these maladies. Most commonly, however, the stomach is attacked in the course of these, owing to errors of diet or regimen, or to the exhibition of irritating or inappropriate medicines or doses. Gastritis becomes, moreover, a prominent feature or complication of several fevers, especially those which have been denominated bilious by some writers, or gastric, owing to this feature, by others; and which are common in autumn or summer, or in warm climates. These fevers may assume a bilio-gastric character at these seasons, and may be either continued or remittent,—the latter chiefly in malarious and warm climates. Indeed, there are few kinds of fever, especially in these seasons and climates, in which the stomach is not more or less prominently affected; and still more particularly in the exanthemata and in pestilential and malignant fevers. (See arts. FEVERS, § 387. *et seq.*, and PESTILENCES.)

30. (*c.*) Mechanical agents may produce gastritis, by having passed into the stomach, or by acting externally. Broken glass, or various sharp or rough substances accidentally or intentionally swallowed, have produced this disease; whilst blows on the epigastrium and region of the stomach; falls, bruises, &c., and the reaction consequent upon such physical shocks, have been followed by similar results. Atmospherical changes, and vicissitudes of temperature, especially when extreme; exposure to cold after the body has been overheated, and even any form of exposure when prolonged, have been considered sufficient to induce, what some authors have described as a catarrhal form of gastritis, affecting the villous surface of the organ,—various physical influences, as electrical states of the air, &c., being supposed by them to aid the operation of vicissitudes of temperature.

31. ii DESCRIPTION. — *Gastritis* has been variously considered, in respect of its *seats and varieties*, by different writers. It has been *divided* into the *phlegmonous* and *erysipelatous* or *erythematic*, by CULLEN, PINEL, GOOD, and J. P. FRANK; by some writers into the *acute* and *chronic*, the phlegmonous being most frequently the former, the erythematic the latter, but to this division there are many objections; and to this correspondence of morbid states there are numerous exceptions. HILDENBRAND admitted three species, namely, the *phlegmonous*, the *catarrhal*, and the *rheumatic*, either of which may be *acute*, or *chronic*, these latter characteristics having reference only to severity of attack and period of duration. The catarrhal form of this writer, corresponded with the erysipelatous of others. BROUSSAIS and ARMSTRONG distinguished two species, *sero-gastritis* and *muco-gastritis*, assuming the serous and mucous coats of the stomach to be respectively the seats of the phlegmonous and erythematic forms of the disease.

32. Of the accuracy of these divisions of gastritis, very reasonable doubts may be entertained, arising from the phenomena observed during the life of the patient, and from the changes seen after death. The manner in which the disease appears, the state of vital energy at the time of attack, and the causes which have induced it, severally aid in determining the forms in which it may be arranged. If the disease supervene upon inflammation of the liver, or omentum, or peritoneum, it may be reasonably inferred that the serous coat of the stomach is first implicated, although it will be difficult to determine how far the other tissues are affected. Or, if gastritis arise from irritating substances taken into the stomach, from the regurgitation of acrid bile, or in the course of a severe dyspepsia, it is obvious that the villous surface is primarily and chiefly affected, although the other tissues constituting the parietes of the viscus often subsequently become more or less implicated. That inflammation may thus extend from either surface, to one or more of the several tissues, of which the parietes of the organ are formed, will be admitted; and that this extension of the inflammation is more frequent than the simultaneous seizure of all the tissues or coats of the viscus, will also be allowed. But it is not improbable, that this latter state of the disease may sometimes occur in a most severe or intense form, and when the causes are of an energetic or poisonous kind. In such cases, although the morbid impression may be directly made upon the villous surface, the whole of the tissues may, through the medium of either the connecting cellular tissue or the organic nerves, soon become affected, the villous coat, however, generally displaying the most marked alterations of structure, or the most evident signs of inflammatory action.

33. *Phlegmonous*, or *acute*, or *active gastritis*, therefore, is not, as *post-mortem* examinations fully prove, limited to the serous covering of the stomach, although often this coat is the tissue primarily or chiefly affected, as when gastritis supervenes upon, or is complicated with, inflammation of one or other of the adjoining viscera. But, in the majority of instances of acute gastritis, occurring primarily or spontaneously, nearly all the coats of the organ are more or less affected, probably in a part only of the parietes, and especially the cellular tissue uniting the coats, and forming

the matrix in which they as well as the nerves and bloodvessels are imbedded. That all cases of acute gastritis, however, do not commence in this manner, but that many, and these even the most severe, may originate in the villous surface, has been stated above (§ 31.). Hence it follows, that the *chronic* form of the disease is not the only form which is seated in this surface; and that, although most frequently thus seated and even thus limited, inflammation of the other tissues may also be possessed of this character.

34. Viewing, therefore, the several forms and states of gastritis, with reference to their causes, and to the modifying influences of season, climate, constitution, diathesis, and previous disease, it may be inferred — 1st, that gastritis, either in its commencement or progress, is not necessarily limited to a single tissue or coat of the stomach, although it may originate in one or other, or affect one or two or more of these tissues in a more marked manner than the rest; 2nd, that the terms, *phlegmonous*, *adhesive*, *erysipelatous*, *erythematic*, *catarrhal*, &c., are not precise as respects the seat and nature of the disease, nor appropriate when we regard the meaning usually attached to these terms; 3rd, that *acute* and *chronic* have no reference to the particular tissue of the organ affected, but refer merely to the severity and duration of the disease; that these terms are extremely arbitrary, and that we have no absolute and precise range of activity and chronicity in respect of this disease, more than of any other; for gastritis may affect the more external, or the more internal coats of the organ, as well as several or all of them, in every grade of severity and of duration, between the opposite extremes of activity and duration of existence.

35. In the following description of gastritis, I shall consider — 1st, the slighter forms of the disease, especially as they occur in the villous surface of the organ; 2nd, the sub-acute or severer states of inflammations, as either supervening on the former, or commencing primarily, and extending to more than one of the tissues of the viscus; 3rd, the most severe, malignant or exasperated attacks of gastritis; 4th, the more prolonged or chronic forms of the disease; 5th, the complicated and consecutive states of gastritis; 6th, the terminations of gastric inflammations, &c. The diagnosis, prognosis, and treatment of the disease, will afterwards be considered in succession.

36. *A.* The *milder or slighter form of gastritis* may chiefly be referred to the villous or internal surface of the stomach. It is generally connected with a weak and sensitive state of the nerves of the organ. It is often consequent upon indigestion, especially when this affection is prolonged or improperly treated; and is then, as well as when it occurs primarily, occasioned by errors of diet, by unwholesome articles, by excesses in food or stimulating liquors, or by hot spices or sauces. In this form of gastritis, the patient complains of general uneasiness, referrible chiefly to the stomach, and especially after having taken food; of nausea, flatulence, distension, sense of heat in the organ; of thirst, dryness of the tongue or fauces; of acid, acrid, or rancid eructations, causing a sensation of acridity or an unpleasant irritation in the throat and fauces, and occasionally vomiting, especially after fluids are taken into the stomach. The tongue is red at the point and edges, and often loaded at the root and centre. Chilliness, general mal-aise, incapability of exertion, heat of the palms of the hands and soles of the feet, a slight acceleration of pulse, and tenderness at the epigastrium on firm pressure, costiveness, lowness of spirits, anorexia, loathing of food, excepting what is relishing or stimulating, and which, when taken, increases the complaint; sometimes vertigo, and palpitations, are more or less experienced.

37. This mild form of gastritis may occur primarily from the causes mentioned above (§§ 25, 26.) or consecutively upon indigestion; or in connection with severe catarrhal or bronchial attacks, with which, especially with catarrhal fever and influenza, it is often a more or less prominent *complication*. It also forms a very marked pathological condition, in connection with others, during the incubation and development of the exanthematous fevers, especially scarlatina and small-pox; and it is a more or less marked complication or pathological condition in gastric, in gastro-enteric, and bilious fevers, and at the commencement of several other fevers (see art. Gastro-enteric Disease).

38. In this form it is presumed that the villous or mucous membrane of the stomach is only affected, and that this tissue is merely in a state of irritation or hyperæmia, and either partially or to a greater or less extent as respects this surface of the organ. It is often relieved or entirely removed in the course of a few days by abstinence or the use merely of emollient articles of food taken in small quantities. But it is often also of much longer duration, either becoming *chronic*, or passing on to more serious disease — to either a subacute or an acute form of gastritis, or to very dangerous organic change. These results most commonly follow, more or less slowly or insidiously, although sometimes rapidly upon injudicious treatment, — upon the use of stimulants and tonics, or upon habitual excesses in food and intoxicating beverages. In many cases the disease continues for months without much increase; in others, the inflammatory action becomes more general over the villous surface, or extends more deeply in the parietes of the organ. The morbid irritation may, moreover, become concentrated in the mucous follicles, and, after an indefinite, but generally a protracted period, may lead to ulceration, and even to perforation of the viscus. In young subjects, especially those who are imperfectly nourished and respire an unhealthy atmosphere, the form of inflammation, existing in an asthenic state, may induce softening of the villous and sub-cellular tissues, with either thickening or even thinning of the coats of the organ.

39. Attacks of mild gastritis, in varying grades of severity, are frequent in persons subject to dyspepsia, or who are guilty of excesses in eating and drinking; and they often subside or disappear spontaneously, shortly after the causes are no longer in operation; the secretions and exhalations from the villous surface and follicles of the organ favouring the occurrence of resolution of the inflammatory condition. Hence abstinence or a moderate abstemiousness is the best mode of cure, unless medicines be prescribed with much caution, and be carefully suited to the morbid conditions, which are generally not merely inflammatory irritation or hyperæmia of the villous coat and follicles, but also weakened or exhausted

energy of the ganglial nerves actuating the organ. As respects either state, it is better that it should be allowed to recover itself, through the influence of vital resistance, than that it should be perpetuated by irritants or otherwise inappropriate means.

40. *B. Sub-acute gastritis* is generally limited to the villous surface, or probably is extended in parts to the sub-villous cellular tissue. It generally results from the same causes as have been already noticed (§§ 25, 26.); and may be present as a prominent affection or complication of the same exanthematous and febrile maladies (§ 28.), and in the advanced stages of tubercular consumption. It may occur primarily, although not frequently; or it may follow the milder form of gastritis, owing to errors of diet or regimen, or inappropriate treatment. It sometimes is consequent upon, or is associated with, œsophagitis, or pharyngitis, or both; and not infrequently it is accompanied with inflammatory irritation or action in the duodenum and small intestines (see art. Gastro-enteric Disease). It is in most respects, as regards its causes, associations, symptoms and terminations, similar to the mild form already described; the difference being only in the greater severity of the symptoms characterising this.

41. In sub-acute gastritis there are pain, or sense of heat at the epigastrium, frequent retchings and vomitings, especially after substances, in any considerable quantity, are taken into the stomach, and the matters brought off the stomach are generally ropy, colourless, and abundant, or coloured by bile of a yellowish or greenish hue. Chilliness or slight shiverings often precede and attend the pain and vomitings, with a sense of anxiety at the præcordia, and tenderness, fulness, or distension at the epigastrium, depression of spirits and of strength, a dark or sallow circle around the eyes, a loaded tongue, the point and edges being red or indented by the teeth, or the surface more generally red, and the papillæ elevated, with great thirst, and desire of cold fluids. The bowels are costive; and the urine is scanty, high-coloured, and generally presents an acid reaction. The pulse is frequent, soft or broad, open or compressible; the skin dry and feverish. The breathing is frequent and shallow; and the patient either sits up for a time or lies on his back in bed. All kinds of food, especially animal food, are loathed; or when tasted, excites nausea or vomiting, which generally also follows warm drinks, especially tea.

42. This form of gastritis is often *complicated* with inflammation of adjoining portions of the digestive villous surface; but it also sometimes occurs *primarily*, and in an uncomplicated form, especially in young subjects, after debauches, or the excessive ingestion of spirituous or vinous beverages; or after copious draughts of cold fluids when the body is perspiring, or even in other states of the frame. It generally subsides when a suitable abstemiousness or abstinence is enforced, or when otherwise judiciously treated. But it may lapse into a more *mild*, but often a more *chronic* state; and even go on to a more severe, or a disorganising form, ultimately *terminating* in some one or other of the structural lesions which will be described hereafter. When associated with inflammatory irritations of the intestinal villous surface, the bowels are more or less relaxed, the febrile symptoms sometimes more marked and attended by frontal headache, and by pains in the back and limbs (see Gastro-enteric Disease). Sub-acute, as well as mild gastritis, although it may affect the coats of the organ to some depth, and in parts only, very seldom proceeds so far as to implicate the serous surface, unless the mucous follicles have become ulcerated, and the ulceration has reached the peritoneal membrane. In this case, the sub-acute state of disease has generally degenerated into the chronic before this advanced lesion has taken place.

43. *C. Acute or severe gastritis* occurs — 1st, primarily or directly from its occasional causes; 2nd, consecutively upon the milder forms of the disease already noticed, owing to the persistence of the causes, or to improper treatment; and 3rd, from the extension of inflammation from adjoining viscera. It may present various grades of severity or violence, owing to the greater or less extension, or intensity of the morbid action, and virulence of the exciting cause, relatively to the state of constitutional power; and, in any of these grades, it may be a prominent affection in the course of the more malignant forms of the exanthemata, of fevers and pestilences. Acute gastritis is rare as an idiopathic malady, and unassociated with inflammation of any other organ, unless when it is produced by poisons, or by substances which, from their quantity or condition, act as poisons, as the ingurgitation of spirits, or of very cold or very hot fluids, &c. M. Andral records a case in which fatal gastritis followed a severe mental shock, the stomach alone presenting the results of inflammatory action.

44. (*a.*) When gastritis is produced by *irritant poisons* (see art. Poisons, § 109. *et seq.*), the local symptoms are instantly developed, and when the poisons are of an acrid or corroding nature, they assume the most intense features. The pain at the epigastrium is most violent, burning, pungent, or lacerating; often extends from the pit of the stomach to the spine, or to both hypochondria, and is attended by extreme anxiety, mental and physical depression; by constant retchings, the matters ejected varying with the contents of the stomach at the time of ingestion of the cause, and with the nature of the cause (see Poisons, § 54.). The retchings aggravate the sufferings, and return on each occasion when the irrepressible thirst impels the patient to drink. The breathing is shallow, and increases the pain; the supine position, with the knees drawn up; or a semi-recumbent posture being generally assumed. The slightest pressure increases the patient's sufferings. The vomitings are most painful, and, after the contents of the stomach are thrown off, consist chiefly of the fluids last taken, sometimes coloured by bile, and containing a little mucus, or glairy matter streaked with blood. With the intensity of the symptoms, the prostration of the patient increases, and the features are more sunk, and expressive of greater anxiety. The epigastrium and hypochondria are generally tumid or tense, and the temperature of these regions is much augmented. The skin is hot, dry and harsh, at an early period, and the cheeks sometimes flushed, whilst a dark circle surrounds the eye, and sometimes also the mouth, the coun-

tenance being expressive of extreme anguish; and distressing anxiety is referred to the præcordium and epigastrium. The tongue is either red throughout, or only at the point and edges, the middle and base being covered by a thick fur. The pulse is frequent, and at first constricted or small. The urine is scanty and high-coloured. The bowels are costive; but, when the cause, especially when it consists of some poisonous substance, has passed the pylorus, and has inflamed the intestinal mucous surface also, diarrhœa, and purging may accompany the retchings and vomitings.

45. As the disease proceeds, the symptoms assume a worse character; and, according to the intensity of the cause, especially when this is of an acrid or corrosive nature, the progress of the disease is rapid, and its duration short; a fatal termination sometimes taking place in a few hours, although most frequently not until the second, third or fourth day, unless in the most violent cases. When the disease proceeds thus unfavourably, the pulse becomes rapid, very small and thready, sometimes irregular, intermittent or slow. The extremities are clammy or cold, whilst the trunk is still hot and even dry. The features are sunk or pinched, pallid or sallow. The thirst and burning heat in the region of the stomach continue, and the pain is attended and aggravated by frequent flatulent eructations, or by hiccup accompanied by eructation, and at intervals, or soon after fluids are taken, by vomiting without much effort, or without retching, the matters thrown off being as if eructated from the stomach. During the disease, the desire of cold fluids, or of iced water continues; and ultimately after hiccup has been present for a short time, the pain is diminished or altogether ceases; but the features, pulse, and temperature, sink more and more. The extremities and surface become more clammy and cold, and the pulse disappears. Death rapidly follows, the mental faculties being unaffected, or continuing without manifest impairment until the last, unless the cause of the attack has been of such a nature as not only to inflame the stomach, but also to disorder the nervous and mental manifestations. When the disease and the operation of its cause are limited to the stomach, or to this viscus and adjoining portions of the digestive canal, death is the result of the extent of lesion or disorganisation, being such as exhaust or depress organic nervous and vital power to such a degree as is incompatible with the continuance of the heart's action; the intimate connection of the affected viscus with the centres of organic nervous power, rendering all severe affections of the former most depressing to the latter, and ultimately annihilating its manifestations, when they reach a certain grade.

46. When acute gastritis is produced by less intense causes, or when it is consequent upon inflammation of the liver, or of some other part, the serous membrane becoming implicated, the history of the disease is modified from the foregoing, gastric symptoms supervening, with more or less severity, upon those characterising the primary malady. The consecutive gastritis thus developed, although often both acute and severe, is seldom so intense as the form now described; and a fatal termination, which is very frequently the result, is generally longer delayed, than when gastritis is produced by the more intense causes, especially by acrid or irritant ingesta. When the disease extends to the serous membrane from adjoining parts, a portion only of this membrane is at first attacked, although the inflammation may soon be much further extended. Whereas when a deleterious substance is taken into the stomach, the injurious effect is more widely extended, and more intense, unless this substance be in great measure intercepted by the contents of the viscus, and thrown off with these contents by vomiting (see art. POISONS, § 51. *et seq.*). When acute gastritis is consecutive of inflammation of adjoining parts, and is not arrested or relieved by treatment, it presents more or less of the characters described above (§§ 44—46.) generally in a somewhat less intense and less rapid form: death, however, often occurring in the course of a few days, or sometimes being delayed to two or three weeks. In some cases the disease may lapse into a sub-acute or even chronic form, and be prolonged to some indefinite period.

47. Acute gastritis may supervene upon either the mild or the sub-acute form; or gastritis in a slight and chronic state may have long existed, and ultimately an acute attack may be developed, owing to the operation of one or more of the causes already enumerated. In some cases, a judicious treatment may reduce the acute attack to the state which preceded it, but more frequently the severe symptoms depress and ultimately exhaust the patient. Primary acute gastritis, when early or judiciously treated, or even when treated in such a manner as may not interfere with the salutary changes brought about by the efforts of nature, and by vital resistance, terminates favourably in many cases, a cooling and soothing treatment with abstinence, bringing about resolution. But not infrequently, the disease either proceeds in the manner above described (§§ 45, 46.), or in a less intense or rapid form, to dissolution; or it is so far ameliorated as to assume a sub-acute, or a mild form. In either of these latter cases, it may be further relieved or altogether removed, or it may continue in a chronic state.

48. *D. Chronic gastritis* is most frequently either the mild or sub-acute state of gastritis rendered obstinate, or prolonged by neglect, or errors of diet or regimen, or by injudicious treatment; it more easily follows an acute attack. In whatever form gastritis occurs — whether mild, sub-acute, or acute — if the cause which produced it be removed, and judicious means be used, the natural secretions of the viscus, by their free and abundant exudation, favour the occurrence of resolution. But if food or drink of an exciting, heating, or irritating kind be administered, inflammatory action is increased or perpetuated, and continues in some one of various grades, and attended by diversified symptoms for a very indefinite period. In its course, moreover, further disorder or disease is developed, or pre-existing disorder is aggravated, and various complications arise.

49. The symptoms referrible to the stomach are often an aggravation of those characteristic of indigestion, or similar to those of the milder forms of gastritis. More or less pain is felt, is generally aggravated by food, or by much fluid, and is attended by heartburn, a sense of distension, and by tenderness on pressure. Anorexia and nausea are present, and occasionally vomiting occurs, the

matters consisting of such as have been more recently taken, or of a glairy fluid with mucus. Instead of pain, a sense of gnawing, of craving, or of sinking, is sometimes experienced; and either of these may be accompanied with flatulent or acrid eructations, with fulness or tension at the epigastrium, or with a feeling of distension, or of heat, and general discomfort. The appetite is either altogether lost, or it is craving, gnawing and morbid, articles which are most inappropriate being desired. These articles generally aggravate the pain, or occasion vomiting, and increase the thirst, which is generally present. A foul or loaded, or furred tongue, the point and edges being red, or indented by the teeth; an unpleasant taste in the mouth, or a vitiated taste; heartburn, or a sense of acidity of the stomach, with frequent acrid, acid, fœtid or rancid eructations; costiveness, or an irregular state of the bowels, the stools being often deficient in bile, or of a very dark bilious appearance, and offensive, are generally experienced. The urine is either scanty, clear and high-coloured, or paler, turbid, or phosphatic. Chilliness and feverishness, frequently with frontal headache; a dry, harsh or scaly state of the skin; general mal-aise, want of physical power, and defective mental energy and application, are commonly complained of.

50. With the continuance of the complaint, numerous sympathetic feelings and disorders are manifested. The several senses are often slightly affected. The mind is always engaged with the bodily feelings, which become exacerbated, or are exaggerated by the constant attention directed to them; the disorder often approaching the characters of hypochondriasis, or even passing into this complaint. The temper is irritable and uncertain. In many cases, the pharynx and fauces present a similar state of chronic irritation, with congestion or inflammation, as may be presumed to be present in the stomach, and the irritation sometimes extends to the epiglottis or larynx, and is perpetuated by the acrid eructations which occur. In these cases, a dry stomachic cough is complained of, a fit of which sometimes is followed by retching or even vomiting. Palpitations, with increased frequency or irregularity of the pulse, are often experienced. Occasionally the tongue presents patches as if deprived of its epithelium in parts. It is generally loaded or furred at its base, and the follicles swollen. Sometimes the surface is red, smooth and shining throughout; or it is variously fissured. The gums are swollen or spongy, and fall or recede from the teeth. According to the severity and duration of the disease, numerous other sympathetic affections are developed, continue for a time and disappear, or become permanent. The disease thus proceeds for an indefinite time, and is either ultimately relieved or removed, or it exhausts and emaciates the patient, and superinduces organic lesions of the stomach, especially at the cardia or pylorus, or disease of the liver, lungs, pancreas, or kidneys; the complication often terminating life.

51. ii. Appearances on Dissection.— The changes produced by the milder forms of gastritis —by the mild and sub-acute—are rarely observed unless when they occur at an advanced stage of some chronic disease, as tubercular consumption, hectic fever, &c. These changes, as well as those which are produced by acute gastritis, have been very fully described when treating of the morbid anatomy of the alimentary canal (see art. Digestive Canal, § 21. *et seq.*), and of the effects of Poisons, under which head the alterations produced by the several corrosive, irritating and other poisons in the stomach are circumstantially detailed. In the more sub-acute and chronic states of gastritis, especially as observed in drunkards, or in persons addicted to excesses in eating, are chiefly a dark, reddish-brown, or slate-grey, or blackish blue discolouration of the villous membrane, thickening, increased condensation or induration of this membrane — an hypertrophy, presenting itself in various grades (see art. Digestive Canal, § 27. *et seq.*). The pyloric portion of the stomach is generally the chief seat of the more chronic inflammation of the stomach, the sub-mucous cellular tissue, and the muscular coat, participating in the hypertrophy, in various degrees, the parietes of the viscus chiefly in and near this portion presenting increased thickness and hardness. In some of these cases, the stomach contains or presents on its internal surface, a greyish, or colourless, glairy mucous secretion, in considerable quantity. In cases of acute gastritis complicating exanthematic fevers, or caused by some kinds of poisons, flocculent exudations, or even partial formations of false membrane, are sometimes found on the mucous surface.

52. Idiopathic inflammation of the internal coats of the stomach, involving chiefly the sub-mucous and connecting cellular tissue, and terminating in suppuration, is very seldom observed. Inflammations thus seated and thus terminating are oftener met with consecutively of, or associated with, some other malady. In these cases, the parietes of the stomach are thickened, owing to the sub-mucous tissue being distended with pus; this tissue being softened and friable. The mucous membrane itself is generally injected and red. In some parts, this membrane is perforated by numerous irregular cribriform openings, through which the pus escapes into the cavity of the stomach. The various organic lesions of the stomach consequent upon gastritis, or upon constitutional or other causes, are fully described under the head Digestive Canal (§ 18. *et seq.*), and, as respects their symptoms and treatment, are considered in the sequel.

53. iii. Diagnosis of Gastritis.— *Peritonitis*, especially when circumscribed or limited to the viscera or regions of the upper part of the abdomen, may be mistaken for gastritis, as the prostation, pain, vomitings, retchings, &c., may be as great in the one as in the other. But the situation of the pain, the great tenderness, especially at the epigastrium, the sense of burning there, the character of the thirst and desire of cold or iced fluids; the mucous and glairy or ropy matters vomited, sometimes streaked with blood, the appearance of the tongue, and the not infrequent recognition of the exciting cause, generally indicate the nature of the malady. When gastritis is consequent upon hepatitis, or splenitis, or omentitis, or diaphragmitis, as sometimes observed, especially upon the first of these, the diagnosis may be more difficult. But the history of the case, and the appearance of severe gastritic symptoms during the course of hepatic disease, or of the other inflammations, will indicate this extension of the morbid action. When more general perito-

nitis is present, the diagnosis is more manifest; inasmuch as the painful symptoms extend much lower, whilst in gastritis they ascend to the base of the thorax, and are generally attended by a greater amount of anxiety extending frequently to the præcordia. When inflammation affects the opposing peritoneal surfaces of stomach and liver, as not infrequently found after death, especially in warm climates, the symptoms are often equivocal in respect of either organ. The complication may, however, be inferred from the characters of the early symptoms, and of those more recently developed.

54. The diagnosis of the milder and more chronic states of gastritis, is much more difficult than that of the acute. The not infrequent temporary relief of pain and other symptoms of the former, by stimulants and carminatives, frequently suggests the existence merely of indigestion or morbid sensibility of the organ, whereas a mild or chronic state of inflammation of the mucous surface may exist nevertheless. But, when pain is present in the region of the stomach, and is increased by pressure, or by food, and by warm fluids; when vomiting of a ropy and abundant mucus takes place; and when the throat, fauces and gums are red or inflamed, this form of gastritis may be truly inferred. The aggravation of pain, or the production of vomiting, by warm tea, or other warm fluids; a dry and scaly state of the skin; the presence of papular or other eruptions on the skin; the relief following the use of cooling fluids, and an abstemious or low diet; the spongy or inflamed gums; the red papillated, aphthous, or fissured states of the tongue; or a dry, red, or smooth and shining appearance of this organ; and heat in the palms of the hands, or soles of the feet, are severally indications of mild or chronic gastritis, especially when observed in connection with slight febrile symptoms, and an alteration in the secretions and excretions.

55. iv. The Prognosis in the milder forms of gastritis, and even in the chronic states, before serious complications have been developed, is generally more or less favourable, provided that a judicious treatment, especially in respect of diet, regimen and air be adopted and persevered in. When, however, organic disease of some vital or important organ has either preceded, or been developed in the course of, these states of gastritis, a very unfavourable issue may be anticipated, or may be near at hand; mild, sub-acute, or chronic gastritis, or gastro-enteritis, or even gastro-œsophagitis, with troublesome irritation of the pharynx or fauces, very commonly characterising the far advanced stage of hectic and organic visceral diseases.

56. In acute gastritis, the prognosis depends much upon the exciting cause. When this is of a very corrosive or acrid nature; when it has not been entirely removed from the stomach, and when this viscus was empty when it was taken; when the injurious matter is not only acrid or irritant, but also depressing to the organic nervous energy, a very unfavourable issue may be expected, even at an early period of the disease. If, however, the cause be altogether removed, and a diminution of the sufferings, or of the vomiting be remarked; and if appropriate means be retained on the stomach — if the painful symptoms abate, and none of the most dangerous appear — if the matters vomited be neither streaked with blood nor sanious — if neither singultus, or cold perspirations be present — if the anxiety, distress and restlessness be relieved — if the character of the pulse, respiration, and of the sympathetic disturbance improve; and if the disease be primary or uncomplicated, a favourable issue may reasonably be expected, if no error in diet or regimen be committed, so as to increase or to rekindle the inflammatory action. When acute gastritis appears in the course of exanthematous or other fevers; or when it is consecutive of hepatitis, or of inflammation of one or other of the adjoining viscera, the prognosis should be extremely guarded, for the extension and complication of disease may be attended by great danger, although the symptoms may not appear very severe. In these cases especially, the extent and exact seat of lesion are not easily determined, the degree of prostration, the character of the pulse, the state of the abdominal surface and of the extremities, the anxiety and appearance of the countenance, the position of the patient, and the nature of the retchings and matters vomited, severally guiding the prognosis.

57. v. Treatment.—The treatment of the several forms of gastritis should be conducted with the same intentions for each; — namely, 1st, to remove the exciting cause; 2ndly, to subdue the inflammatory action produced; 3rdly, to avoid whatever may irritate or excite the stomach by its properties, or the quantity taken; and, 4thly, to restore the healthy functions of the organ.—*A. The milder forms of gastritis* are generally caused by errors of regimen, especially in respect of food and drink, and, in many cases, they require merely abstinence, or a mild, farinaceous, and abstemious diet for their removal. But, in some constitutions, and in others where abstemiousness is not observed, the complaint, although mild at first, becomes either chronic or exasperated, and, in addition to a strict regimen, various other means are required. These means should be suited to the age, constitution, and power of the patient, and the severity of the disease. Generally, the application of leeches over the epigastrium, followed by rubefacients, especially the terebinthinate embrocation, and the administration of emollients, with refrigerants, &c. are sufficient to remove the milder states of disorder. Small doses of the nitrate of potass, given in the mistura amygdalæ, with hydrocyanic acid, are usually of service. The bowels should be kept freely open by means of cathartic enemata. A moderate dose of calomel may be given at bed-time, early in the disease, especially when the functions of the liver are impaired; and its operation may be increased by about twenty or thirty grains of calcined magnesia in the morning, followed by a glass of lemonade immediately after the magnesia is taken; or a drachm of citrate of magnesia may be prescribed in any mild vehicle. Even when retching or vomiting is present, the above means usually afford relief in a short time; especially when the *third* indication is duly enforced, and abstinence is observed, the mildest farinaceous articles only being taken in small quantity.

58. *B.* In the more *acute* or *severe cases* of gastritis, the removal of the exciting cause should be instantly attempted; and if this be of a poisonous nature, the means advised for this purpose

in the article Poisons ought to be employed. Vascular depletion should be promptly ordered, the amount being regulated by the age and strength of the patient, by the state of the pulse, and more especially by the nature of the exciting cause. In most acute cases, and at an early period, one general *bloodletting*, which may be followed by the application of leeches to the epigastrium, or by a repetition of the local bleeding, and by a blister, or a rubefacient embrocation or epithem, is requisite. In some cases, especially when the disease is not occasioned by poison, a full dose of calomel, at an early period, is of much service, and tends remarkably, especially when given with magnesia in the form of powder, to allay the irritability of the stomach: but medicines should be sparingly given by the mouth, those already mentioned (§ 57.) being the most appropriate. When the vomiting is urgent, and the sense of heat at the stomach great, the nitrate of potash may be given, as above combined, more frequently, and two or three drops of tinctura opii may be added to each dose. But the quantity of the vehicle should be small and emollient or mucilaginous, and effervescing mixtures or large draughts avoided. Small morsels of ice, and the citrate of ammonia, or of soda, or of magnesia, in weak solution and in small quantity, are generally beneficial, the latter especially when the bowels are not sufficiently open.

59. At an advanced stage of acute gastritis, when vomiting is almost constant and without much effort, or when blood is brought up with other matters, or when the pulse is sinking or irregular, it becomes a question what means should be adopted, or whether any can be of service. In these almost hopeless circumstances, where fatal disorganization of the stomach is expected, I have sometimes prescribed the spirits of turpentine by the mouth, in small and repeated doses, in the form of an electuary with aromatics (see art. Spleen, § 69.), and a turpentine epithem to be applied at the same time over the epigastrium and abdomen. In many instances, such doses of tinctura opii as the peculiarities of the case may suggest, and very small doses of creasote, may be added to the electuary. (*See Author on the Use of Terebinthinate Remedies in Disease; in Lond. Medical and Physical Journal for* 1821.) In several instances, when this treatment has been prescribed in these circumstances, the vomiting has ceased almost immediately, and the patient has ultimately recovered.

60. *C. The chronic states of gastritis* require means which their antecedents and causes chiefly should suggest. In some cases, especially when indications of exacerbation from errors in regimen present themselves, leeches applied on the epigastrium are necessary, and the repetition of them, after various intervals, should not be overlooked. Generally, a few leeches, and a frequent repetition of them, are more beneficial than a great number applied at one time. After these, warm embrocations, rubefacient plasters, or even blisters, are of service. But in most of the chronic states of the disease, whether simple or complicated, diet and regimen should receive the strictest attention. In some instances, the mild preparations of mercury suitably combined with gentle laxatives or aperients, are of great service, and when the liver is torpid, they can hardly be dispensed with. When chronic gastritis is complicated with enlargement of the liver, calomel, or other mild mercurials, conjoined or alternated with purgatives, and aided by the deobstruents advised for this state of the liver (see Liver, § 245. *et seq.*), should not be omitted.

61. *D.* In most cases, when *pain* or *spasm* is referred to the stomach in the course of this state of disease, hydrocyanic acid, in mucilaginous or emollient mixtures, or with a weak solution of any of the alkaline carbonates, or with lime-water and milk, is generally productive of benefit. In these cases, also, the nitrate of bismuth, or the oxide or nitrate of silver, combined with very small doses of ipecacuanha (from the sixth to the quarter of a grain), and opium or henbane, is of great service. The oxide or the sulphate of zinc, in small doses, is also very beneficial, when combined with anodynes. Dr. Wood remarks, respecting the nitrate of silver, that from a quarter of a grain to a grain is often administered two or three times a day with advantage. Cures in most obstinate cases have been obtained from this substance. It has appeared to be most serviceable in those cases which are attended by vomiting, and in which the tongue is smooth and glossy, as if deprived of the papillary structure. I have, for many years, been in the habit of prescribing the nitrate intimately triturated with narcotics in these cases, and in the chronic states of gastritis complicated with palpitation, or with irritation of the intestinal mucous membrane.

62. When convalescence commences and advances, the mild vegetable tonics, especially the infusion of calumba or of cheireita; subsequently the chalybeate preparations; and the diet, regimen, and mineral springs, or artificial mineral waters, advised when treating of Indigestion and Hypochondriasis, should be resorted to, according to the circumstances of each case. In most instances, travelling, change of air and of scene, gentle but agreeable mental occupation, relaxation from the anxieties and mental tension of continued application to business, moderate exercise in the open air, and diversion of the mind from such feelings and slight dyspeptic disorders as generally attend convalescence from gastritis, are generally most beneficial, and always requisite for a very considerable period after inflammatory affections of the stomach.

III. Organic Lesions of the Stomach. Classif. — IV. Class. I. Order (*Author in Preface*).

63. *Alterations of structure* seated in the stomach are frequently the consequences of inflammation; but they may, in other cases, result from chronic irritation, and, in different circumstances, from vital depression, or from constitutional taint. Cancerous lesions proceed chiefly from this last cause, aided probably, or at least in some instances, by prolonged irritation, or by impaired vital power. Organic lesions of the stomach may thus be viewed as the more or less remote results of *Indigestion*, of *Hypochondriasis*, of *Morbid Appetite*, of *Pyrosis*, and of the *Nervous*, *Spasmodic* and *Inflammatory affections* now passed in review. Consequently, the Causes of these organic changes are those which are productive of the primary affections from which they spring.

64. The *Stomach* is liable in a very marked, and

in a very special manner, to all the lesions which I have fully described when treating of the *structural alterations* of the DIGESTIVE CANAL. To that article I must refer the reader, for a general description of the lesions implicating the stomach; but some of those are so frequently seated in this viscus, or in its cardiac and pyloric orifices, and occasion special forms of suffering, as to require particular consideration at this place. Of these lesions the most important are, *ulceration* and *perforation*, *softening* and *disorganization*, *thickening*, *scirrhous degeneration*, and *carcinoma*, of the parietes or of the orifices of the stomach.

65. i. ULCERATION AND PERFORATION OF THE STOMACH. — *A.* Ulceration is very rarely an acute disease when seated in the stomach, and it is generally single, or very seldom consisting of more than one, unless when seated in the follicles. The *form* of the ulcer is usually round or oval, but it is sometimes irregular, rarely linear. It may exist in any part of the viscus. Its *margin* is either greyish, pale red, or of a deep brown, and of natural thickness and consistence, or softer, thinner, harder, or thicker than natural. In some cases the surrounding subvillous tissue is thickened and indurated. The *bottom* of the ulcer consists of different tissues, according to the depth the ulceration may have penetrated. In some instances, it is so slight, as to appear as an abrasion; more frequently, however, the villous coat is penetrated, and in some the submucous, the muscular, and even the peritoneal coats, are successively penetrated. When this last tunic is reached, as well as previously to this stage, various appearances and changes are developed which are fully described under the head DIGESTIVE CANAL (§ 37. *et seq.*). The ulceration may thus proceed to perforation, without or with adhesion of the opposite surfaces of the peritoneum, around the seat of perforation. In anæmied or cachectic persons, and not infrequently in chlorotic or anæmied females, adhesions are not often formed, and the ulceration proceeds, without manifest signs of inflammation or increased vascularity, and the coats are corroded, as in phagedenic ulceration, until the peritoneal lining is either softened, or ruptured from distension of the stomach, or during an attack of vomiting following a meal, and a portion of the contents of the viscus passes into the peritoneal cavity, causing peritonitis and death in a short time. The ulcer in many of the cases presents the appearance as if the ulcerated portion were punched or stamped out of the gastric parietes, the margins often presenting no further changes than slight discolouration or injection sometimes with thickening of the cellular issue.

66. The ulceration may be *cicatrised*, as shown in the article just now referred to (§ 39.), or it may proceed onwards, after adhesions have been formed between the opposite portions of the peritoneal membrane, and thus the ulceration may proceed not only to perforation of the stomach, but also to perforation of a contiguous portion of the digestive canal, as the colon, or to more or less ulceration or perforation of another organ. In a female under my care during two or three years for severe dyspepsia, with recurring attacks of chronic gastritis, attended by vomiting, the paroxysm of vomiting being ultimately accompanied with discharges of blood, and the patient having been carried off by a violent attack of hæmatemesis, a large and deep ulceration was found in the stomach, which passed far into the substance of the liver, the peritoneal surfaces being firmly agglutinated around the perforation, and several of the vessels of the liver eroded. Where the bottom of the ulcer thus becomes agglutinated to an adjoining viscus, the contents of the stomach are thereby prevented from passing into the peritoneal cavity.

67. Of the various modes in which ulceration may take place, and of the consequences of this lesion, I cannot add anything to what I have minutely stated elsewhere (see DIGESTIVE CANAL, §§ 37—44.). I may, however, briefly remark, that, although usually commencing in the villous surface, ulceration and perforation may originate in a different situation, and proceed in an opposite direction, as when an abscess in the liver, or in the spleen, opens into the stomach, by the adhesions and perforations produced by the purulent collection. But there is even a *third* mode, not hitherto described, in which atheromatous or fatty deposits in the coats of an artery favour rupture of, or exudation of blood from, the diseased portion of vessel, whereby the villous coat is perforated or torn, and hæmorrhage into the stomach takes place. In rare cases, the hæmorrhage ceases, but the part from which it proceeded becomes the seat of ulceration, which may advance more or less, or even terminate in perforation. Ulceration and perforation of the stomach thus presents the following varieties:—1st, Erosion of the mucous membrane only, consequent upon chronic gastritis. 2d, Small ulcers, with red margins, more or less numerous, and scattered over an uninflamed surface, resulting from irritation or inflammation of follicles. 3d, Much larger ulcers, penetrating the muscular, or even the peritoneal coat, and often having the surface or substance of an adjoining viscus, as the liver, for their bottoms, or perforating a different portion of the canal, adhesions having formed around the ulcers: these are commonly single, oval, or round, are most frequently seated in the small curvature, or near the pylorus, and present no cancerous characters. 4th, Ulcers with ragged and inflamed margins, caused by corrosive poisons, and seldom penetrating the parieties of the stomach. 5th, Ulceration and perforation from without inwards, generally caused by an abscess of the liver opening into the stomach, adhesions of the peritoneum having formed around the ulcerated portion. 6th, One or more small ulcers, caused by atheromatous or fatty changes in the coats of the vessels, and by rupture of the villous membrane. 7th, Gelatiniform softening of the coats of the viscus. And 8th, Carcinomatous ulceration, &c. (§ 77. *et seq.*)

68. *B. The symptoms* of ulceration of the stomach are very equivocal. Several cases of this lesion have come under my observation; most frequently, however, when they have gone on to perforation and its consequences. They have occurred most frequently to females engaged in needlework, or as domestics. In most instances the patients have been more or less anæmied, or subjects of chlorosis, or of irregular, or painful, or scanty menstruation; and, although they had previously complained, for a longer or shorter period, of attacks of gastrodynia, or of spasm of

the stomach, or even of attacks of vomiting, or of hæmatemesis, they have generally been able to pursue their avocations, and to take their food, up even to the period of the fatal seizure. The painful symptoms in these cases, as well as the attacks of vomiting or of hæmatemesis, usually followed a meal; and even when anæmia or cachexia was very manifest, no emaciation was generally present, the patient presenting much plumpness with the anæmia. The forms of ulceration and perforation, from the external to the internal tunics, and from disease of the vessels, are seldom observed, unless in persons of middle age, or far advanced in life; whereas the foregoing occurs most frequently in young females, although it is also met with in persons far advanced in age, and in males. In these there are generally evidences of a cachectic condition, and of a poor or morbid state of the blood. In addition to the symptoms already mentioned, in some cases, a gnawing sensation at the epigastrium, emaciation, flatulence, and various other dyspeptic disorders are experienced; but the appetite is often not much impaired, and, in some instances, neither the pain nor the vomiting is severe until the peritoneal covering is reached, or until perforation and its consequences occur. The attacks of hæmorrhage, in connection with one or more of the symptoms already mentioned, are amongst the most certain indications of the lesion. But it should not be overlooked that hæmatemesis occurs chiefly when much blood is poured out from the ulcerated part in a short time; for when the hæmorrhage is slight, frequent, and prolonged, the blood may pass the pylorus, and either be partially digested or more or less changed, and, mixing with the stools, be altogether overlooked. In this way, much of the anæmia observed before the fatal issue may be produced, hæmatemesis being either slight or altogether absent. When the hæmorrhage is not great, the matters vomited often have the appearance of coffee-grounds; and, in most cases, even when vomiting does not occur, the stools present a black or pitchy hue. These symptoms also attend malignant ulceration or carcinoma of the organ; but the absence of circumscribed hardness or tumour, and of the other symptoms of this latter malady (§ 78. *et seq.*), will assist the diagnosis.

69. *C. Treatment.* — The indications of cure are the same as advised for chronic gastritis (§ 60. *et seq.*). Mild farinaceous articles of food, or such diet as the patient finds to agree the best, and a judicious recourse to sedatives or narcotics, are the means most generally appropriate. The vomitings, especially of blood, often require to be arrested, and, with this intention, the means advised for *hæmatemesis* (see art. HÆMORRHAGE, § 174. *et seq.*) may be resorted to; or the spirits of turpentine may be exhibited in any suitable form, with or without small doses of creasote. If indications of perforation are manifested, by the occurrence of the symptoms of circumscribed or general peritonitis, large or repeated doses of opium, as recommended by Dr. STOKES, are chiefly to be relied upon, with such other aids as are advised when treating of this subject in the article on PERITONITIS.

70. ii. SOFTENING AND DISORGANIZATION OF THE COATS OF THE STOMACH.—This subject has received attention when treating of the organic lesions of the DIGESTIVE CANAL (§ 35. *et seq.*).—*A.* This lesion occurs, as a primary disease, frequently in infants and children, most commonly soon after weaning, or after change of diet; but it may take place at any age, from two months and upwards, in children that have been improperly fed, or nursed by unhealthy females, especially in low, humid, close, and otherwise unwholesome localities. It supervenes also in the course of other infantile diseases, by which it is often masked, or which it may to some extent replace; and it is occasionally observed in the diseases of adults, but generally as a consequence or a contingency of their far advanced progress, as of tubercular consumption, &c. It is, in children, often a severe form of what has been commonly called the "*Weaning Brash*," or the "*Atrophia Ablactorum*," of Dr. CHEYNE. This disease was first correctly described by M. CRUVEILHIER, and termed *gelatiniform softening of the coats of the stomach*; and by Dr. JOHN GAIRDNER, of Edinburgh. About the same time it was also noticed by JAEGER, ZELLER, and others referred to in the *Bibliography*. The softening extends, more or less, to all the coats of the viscus, and is most frequently observed in the vicinity of the spleen. The coats may not be only softened, but they may even be so eroded as to give rise to *perforation* at one or more points. In most cases, however, it is very difficult to determine how far the softening and disoganization have existed during life, and how far they may have been a *post-mortem* change. I have met with many cases of this malady, both primary and secondary, at the Infirmary for Diseases of Children, under the circumstances just mentioned, and I believe that the softening often exists to a considerable degree previously to death; but the advanced stage of disorganization, and more especially erosion and perforation, are early consequences of dissolution, which the fluids of the stomach may have been, more or less, concerned in producing.

71. *B.* This disease is met with most frequently in children between the ages of four and eighteen months, owing to the causes just mentioned; and it appears to be more prevalent in July, August, September, and October, than in the other months of the year. From the localities which favour its development, and the seasons which influence its prevalence, this lesion may be said to be almost endemic in certain places, and epidemic in some seasons. It may appear in the course of infantile remittent fever, of hydrocephalus, or of chronic bronchitis; or it may follow the cholera infantum, or scarlet fever, or diarrhœa, especially after weaning, or when the infant has not enjoyed the advantage of a healthy nurse, or is being brought up by hand.

72. *B. The symptoms* of softening of the gastric tunics are, during the earlier stages, chiefly, loss of appetite, mucous or muco-bilious vomiting, and diarrhœa, the stools being liquid, green, or curdy, and offensive; excessive thirst, progressive debility, prostration, pallor, flaccidity and coolness of the skin; occasional flushes of heat, alternating with chilliness; somnolency or lethargy, attended by uneasiness; a disposition to dose, with the eyes half shut, and the pupils turned upwards, &c. When the disease is more fully formed, the countenance expresses pain or uneasiness; the

look is languishing or sorrowful; and the child whines frequently, and is fretful. He is roused from his somnolency by the slightest touch, and, if any one looks steadily at him, even from a distance, he cries, and changes his position. His faculties and senses are unimpaired, but he is peevish and distressed. The absorption of fat is excessive; the eyes are sunk in their sockets; the pupils are contractile, and there is no strabismus. Emaciation and flaccidity of muscles proceed rapidly; the lips and tongue become dry and cracked; and the vomiting of the food is frequent; the stools still continuing green, with shreds resembling spinach and slime: the urine is generally scanty. The pulse is at first slow, sometimes intermitting, but it becomes very quick and small towards the close. Flatulence and hiccup sometimes accompany the vomiting, and cough is not infrequent. The respiration is not materially affected until near the termination of the malady, when it becomes quick and laborious. The abdomen is rarely much swollen, although it generally is flatulent, and resonant on percussion. Ultimately, a pallid and shrunk countenance, red or inflamed eyelids, emaciated, flaccid, and cold extremities, a fluttering pulse, very quick breathing, restlessness, or somnolency, passing into insensibility, terminate life, generally in a very few days, and sometimes even in a few hours.

73. *B. On Dissection*, the appearances observed vary with the circumstances and associations of the disease, — as it is primary or consecutive of some other malady, — and with the period which has elapsed from dissolution. Although the changes cannot be altogether ascribed to dissolution, on the one hand, or to the action of the gastric juices on the other, they may be heightened by either, or even by both. That they exist, to a greater or less extent, in respect even of all the coats of the stomach, but especially the villous and cellular tissues, and that they amount to a very manifest loss of the vital cohesion of these structures, I have been convinced by a careful observation of the phenomena preceding death, and by examination made as early as ten or twelve hours after death. The softening and dissolution produced by the gastric juices after death have been described under the article DIGESTIVE CANAL (§ 41.), and are chiefly observed in the most depending parts of the viscus. But the gelatiniform softening found after death in cases which have presented the above symptoms, either as a primary malady, or as an epi-phenomenon in the course, or at the close, of some other disease, has evidently commenced with the development of these symptoms, and has advanced until it was incompatible with the continuance of life. As it is generally the only or chief lesion found on dissection in the primary cases, and as it has been found in a very marked form even when the examination has been made a few hours after death, there is every reason to infer that it has commenced and existed previously, although it may have advanced further after death had taken place. The situation of the softening, in some cases, precludes the opinion that it could have been produced by the action of the gastric juices; and if it have been thus caused, to what other lesion can the severe, rapid, and fatal symptoms characterising the primary cases be imputed, seeing that none besides it can be detected either in the digestive organs or elsewhere, at least none sufficient to produce death? It should not be overlooked, also, that similar softening, although much less remarkable and extensive, is sometimes found, in these cases, in some portions of the duodenum or of the small intestines; and is to be referred to the same states of vital action, &c. (§ 74.) as produce this lesion in the stomach.

74. Viewing, therefore, this alteration of the coats of the stomach as a primary, as well as a consecutive disease, the question arises as to the nature of the change, — whether is it inflammatory, or is it the result of a vital impairment of the coats of the organ? or is it an association of both, a form of asthenic or cachectic inflammation? That it is not inflammatory is shown by the absence of vascular injection. That it proceeds chiefly from vital exhaustion, with impaired nutrition and cohesion of the tissues, may be inferred from the appearances after death; but it cannot be admitted that the whole amount of change is thus produced, as it may have been heightened immediately, or soon after death, especially when the change is most remarkable. This lesion, however, should be carefully distinguished from *solution of the coats of the stomach by the gastric juices after death*. This *post-mortem* change, which has been described when treating of the alteration found in the DIGESTIVE CANAL (§ 35. *et seq.*), may occur after death from any cause, and in cases that have presented none of the symptoms attending the disease now being considered; but it may take place also in cases of this disease, and may either increase the softening previously existing, or even attack another portion of the parietes of the organ to which the gastric juices have gravitated.

75. *C.* The *Treatment* of the combination and procession of morbid phenomena, constituting this disease, whatever may be the amount of organic change existing previously to death, or occurring subsequently, is the matter of chief importance. For cases frequently occur (and I have seen many of them, both in public and private practice) presenting all the symptoms of this disease, in greater or less severity, and proceeding with proportionate rapidity, for some of which treatment has been successful at an early period, others having gone on to a fatal issue, and manifested softening of the coats of the stomach, without either vascular injection or thickening, and often with diminished vascularity and unusual pallor of the tissues (*see* DIGESTIVE CANAL, § 35. *et seq.*). When an opportunity is afforded the physician to treat the early stage of the disease, or even a more advanced state, more or less benefit will be derived from a healthy and young wet-nurse, the infant always sleeping in her arms. If, however, such a nurse cannot be obtained, or if the child cannot take the breast, ass-milk, warm from the animal, slightly diluted either with simple water or with lime-water, should be given at regular intervals; and various tonics astringents, and antacids be exhibited in the intervals. The diet, consisting of various farinaceous articles, should be carefully attended to taking care not to load the stomach, so as to favour the occurrence of fermentation or acidity. When the ass-milk is taken in sufficient quantity, but little more food is required, and sweets

should always be avoided. The medicines which I have found most beneficial are cretaceous mixtures or powders, with small doses of cascarilla, cinnamon, and a very minute quantity either of creasote, or of tannin, or of capsicum. In some cases, especially when the urine has been ammoniacal, or contained much of the phosphates, I have prescribed small doses of the pyroligneous acid in an infusion of cascarilla or cinchona, or of the nitro-muriatic acids in the same or similar vehicles, or the muriated tincture of iron, with infusion or tincture of calumba. The great difficulty in these cases is to arrest the vomiting and diarrhœa; but this cannot be accomplished by sedatives, and narcotics are most injurious to young children. In some cases, however, especially in older children, the hydrocyanic acid may be given in suitable doses, with the sesquicarbonate of ammonia, and with tonics and astringents. The irritability of stomach in this disease is more readily relieved by stimulants and tonics than by other means; and even the oleum terebinthinæ will often arrest this state when other means have failed. In most instances, also, aromatics should be given with cretaceous and alkaline medicines, and a terebinthinate embrocation may be applied to the epigastrium. If these means should confine the bowels, the risk of increased irritability of the stomach may be thereby incurred, and therefore suitable enemata ought to be administered, if the stools be insufficient or much disordered. In other respects the treatment should be directed, and the regimen conducted, as advised for Indigestion, and above for nervous or functional affections of the stomach (*see* § 14. *et seq.*). In every instance, the more remote causes of this malady, arising either from the locality or the circumstances of the case, ought to be carefully ascertained and removed as far as possible, and change of air, especially to a temperate, pure, and dry air, should be advised, with the use of chalybeate medicines or waters, or such other means as are most likely to improve the vital cohesion and tone of the coats of the stomach.

76. When we have any reason to infer from the state of the stools, or other symptoms, that more or less softening, or loss of vital tone, extends to the mucous surface of the intestines, the means now advised, aided by such others as have been recommended when discussing the treatment of *chronic* Diarrhœa (§ 29. *et seq.*), or of *asthenic* Dysentery (§ 88. *et seq.*), will often be found appropriate and successful.

77. iii. SCIRRHOUS, CANCEROUS, OR MALIGNANT LESIONS OF THE STOMACH. — *Cancerous and Cancroid Growths*, Prof. Bennett.—*A. Carcinomatous and malignant formations of various kinds* are formed in the stomach, especially in or near the cardiac and pyloric orifices, and probably commence, especially the scirrhous and scirrho-carcinomatous kinds, as I have contended when describing them under the head Digestive Canal (§§ 50, 51.), in hypertrophy of the subvillous cellular tissue. The scirrhous change either originates in, or is superinduced by, degeneration or modification of nutrition and secretion, consequent upon prolonged irritation, morbid diathesis, advancing age, and depressed vital power. The several kinds of malignant growths have been found in the coats of the stomach (*see* arts. Cancer and Scirrhous and other Growths). The scirrhous forms are most frequent in the pyloric extremity of this viscus; whilst the medullary, the milt-like, the fungoid, the colloid, the hæmatoid, and other modifications of the encephaloid form of cancer, may commence in the cardiac orifice, or in any part of the gastric parietes. Whilst scirrhous and scirrho-carcinomatous degeneration is generally of slow progress, and occurs in advanced age, the medullary, encephaloid, or fungo-hæmatoid (*see* art. Fungoid Disease), occurs at any age, but more especially in early age, is more generally developed in the form of distinct tumour, is more rapid in its progress, and often appears simultaneously or consecutively in different parts. *Perforation* of the stomach may occur as a termination of malignant disease, especially of the carcinomatous form of ulceration (*see* § 86. *et seq.*).

78. *B. The symptoms* of malignant disease of the stomach are often very equivocal during the early progress of its several varieties; and it is often not until the lesion is far advanced that they can be relied upon. The chief symptoms are—1st, Pain at the epigastrium or its vicinity; 2d, Indigestion, loss of appetite, flatulence, acrid eructations, nausea, and vomiting; 3d, The presence of a tumour in or near the gastric region; and 4th, Emaciation and a cachectic or yellowish anæmic hue of the surface; and various other constitutional phenomena.

79. (*a.*) The *pain* at the epigastrium is generally gnawing or burning, sometimes lancinating. Occasionally, and at first, it is not much complained of, unless pressure is made on the stomach; and often the slightest pressure cannot even then be long endured, although no acute pain is thereby produced. The pain may be increased either by an empty or by a full state of the viscus. Sometimes the pain recurs at intervals, and becomes remarkably severe. In many cases it extends to the hypochondria, or to the back, or along the œsophagus. In others, especially the cancerous or carcinomatous, a lancinating pain is present at an early period, and is amongst the first symptoms to announce the nature of the malady. In the fungoid or encephaloid disease, pain is often slight or almost wanting.

80. (*b.*) The *symptoms of indigestion*, as anorexia, nausea, vomiting, &c., are often amongst the earliest; but they cannot be relied upon, as they may be absent to the very close of the malady. MM. Chardel, Cruveilhier, Andral, and Ferrus state, that they have met with cases in which no more severe symptoms than those of slight indigestion had been present up to the period of dissolution. Such instances are very rare; but I have seen cases in which vomiting had not occurred until very shortly before death; the matters vomited having been then very dark and grumous, or sanious, from the exudation of blood from the diseased part. The vomitings which accompany malignant disease of the stomach have been ascribed to obstruction of the orifices of the viscus. They doubtless very often are dependent upon this cause, but they often also occur where these orifices are free, or where the lesion is seated in other parts of the parietes. When vomitings are not frequent or are absent, it may be presumed that the pyloric orifice is free. When, however, vomitings occur

some time after the ingestion of food, with marked frequency or constancy, and nearly after the same interval, then disease of this orifice may be suspected.

81. When the ingesta are returned immediately after having been swallowed; when deglutition is followed by a sensation of obstruction under the lower part of the sternum, or by a feeling that the food does not pass into the stomach; when the aliments are ejected instantly without change, and mixed with some glairy mucus; or when there is much nausea, without much evacuation by the mouth, excepting glairy matters; then it may be inferred that the disease is seated in the cardiac orifice of the stomach. In these cases the pain is more limited to the epigastrium and beneath the sternum, often extending to the back.

82. The characters of the vomited matters vary with the seat, nature, and progress of the malady. When the pylorus is the seat of lesion the matters thrown off may be more or less digested, but at a far advanced period, or shortly before death, the ejected matters contain altered blood, and present numerous brown or black minute flakes, ultimately passing into the appearance of coffee-grounds, or nearly resembling the black vomit of pestilential fever. In the fungoid or encephaloid form blood is often poured out in larger quantity, and occurs in a purer form or less altered, in the ejected matters, thus closely resembling the hæmatemesis of simple ulceration of the stomach, from which, however, it is generally distinguished by the existence of tumours in the gastric region, in this malignant form of lesion.

83. (*c.*) The presence of *tumour* in or near the epigastrium is an important symptom of malignant disease of the stomach. When scirrhous induration or other form of malignant tumour exists in the pylorus, then it may not be detected at the epigastrium; but, owing to its density or size, and to the extreme distension of the viscus, it may have descended much lower, or even somewhat to either side, according to the position of the patient. Malignant disease may, however, exist in any portion of the parietes of the organ, without occasioning much tumour, and even when it does to a moderate extent, it may not be detected, unless when the patient is very much emaciated, which is not always the case; and when it is detected, it is often difficult to distinguish it from tumour of the pancreas, or of the liver, or spleen, or of the omentum.

84. (*d.*) The *cachectic* and anæmied character of the countenance and general surface, and the peculiar earthy *odour* sometimes exhaled from the body, are observed chiefly at an advanced stage of malignant disease, and are to be attributed chiefly to the constitutional taint, and to the alteration and deficiency of the blood, these changes not being always attended by emaciation, although they are more frequently thus attended. This appearance, however, very generally accompanies malignant lesions of other organs; and it is, therefore, from the association of it with the other symptoms already noticed that the seat of the present malady can be inferred.

85. (*e.*) *During the progress* of the malady the symptoms often vary much: certain of them become more severe, others are alleviated; and the severity of the disease is for a period somewhat abated. But after an uncertain period, and after some error in diet and regimen, or after mental emotion, the symptoms recur with increased severity, or even additional phenomena are observed, especially aggravated pain, vomitings, eructations, borborygmi, hiccup, constipation of the bowels, colicky pains, &c. When the disease is seated in the pylorus, its progress is not merely slow, but the character of the vomiting is generally different. Food may not be thrown off the stomach during the early course of the malady, or not until the orifice becomes much contracted or obstructed, or nearly the close of life; and generally vomiting does not occur until a considerable period after food has been taken. Very frequently, also, articles which have been taken several or many hours previously are thrown up more or less digested, whilst those which have recently been taken are retained. This, very probably, is owing to the circumstance of the latter being directed to the fundus of the viscus, whilst the former having been digested, and having reached the diseased pylorus, are thrown backwards and upwards to the cardia.

86. (*f.*) The *duration* and progress of the malady depend much upon the seat and nature of the lesion. If it be seated in or near the cardia, and if it be the encephaloid or fungoid variety, the duration is much shorter than when it is of a scirrhous or scirrho-carcinomatous nature, and is seated in or near the pylorus. In the former, also, the pain is less acute, and the hæmorrhage is earlier and more distinct, than in the latter. Cancerous ulceration may supervene in either variety of malignant disease, and may go on to *perforation;* but in these, neither is lymph thrown out, nor are adhesions formed, so as to prevent a communication with the peritoneal cavity. Perforation, however, seldom occurs, death generally taking place before the carcinomatous ulceration has proceeded so far. During the progress of the malady, costiveness, or even constipation, is a most troublesome symptom; but occasionally when the pylorus is not obstructed, or when its valve is destroyed by ulceration, a portion of the sanious discharge from the ulcerated parts pass into the intestines and occasion colicky pains, diarrhœa, or dysenteric stools, and accelerate the fatal issue. When perforation of the parietes of the stomach is produced, violent peritoneal symptoms are immediately occasioned, and soon terminate life.

87. The duration of the malady can rarely be ascertained with precision; for dyspeptic symptoms, of greater or less severity, and more or less numerous, always precede the manifest development of malignant disease, which even may not be distinctly declared until shortly before death. The antecedent dyspeptic symptoms are generally thus present for years before the nature of the disease can be ascertained, and when ascertained death may ensue in a few weeks or even days. The duration of the malady is, however, rarely less than several months, and is generally as long as several years. When it is seated in the cardiac orifice, and nearly obliterates the passage into the stomach, the duration is much shorter, and the sufferings of the patient most distressing, and the emaciation greater. But several months or even years may elapse before the lesion has advanced so far as to amount to this extreme pitch.

88. *C.* The *Diagnosis* of cancer of the stomach is

sometimes very difficult; for when there is no tumour detected it may be mistaken for chronic gastritis, or for simple ulceration of the stomach; and when there is tumour, the pancreas, liver, or spleen may be its seat. For either instance it is impossible to assign infallible diagnostic signs. The history of the case, the association and procession of the symptoms, the nature of the causes and antecedents, the *juvantia* and *lædentia*, and the constitutional symptoms, in either state of disease, will chiefly guide the attentive observer. Generally, the discharge of blood from the stomach is much greater in simple ulceration than even in the hæmato-fungoid variety of malignant disease. In the great majority of cases, also, no blood is found until a far advanced stage, or until shortly before death, and then the blood presents the coffee-ground or minute flaky appearances already noticed, occasioned by its minute quantity and altered character. If considerable hæmorrhage occur in the advanced stage of fungo-hæmatoid cancer, or of other varieties, there is generally more or less tumour or hardness, which may often be detected upon a careful examination. But it must be admitted that hæmatemesis may, and does, often accompany tumour of the spleen, liver, and pancreas, more especially the spleen and liver. The various circumstances and peculiarities of the case, of its progress, and of its concomitants, will be duly considered by, and will guide, the cautious and observing physician.

89. *D.* The *Causes* of malignant disease of the stomach are chiefly those which I have fully stated when treating of CANCER (§ 23. *et seq.*) and FUNGOID DISEASE (§ 16. *et seq.*). To these places I refer the reader; but I may very briefly notice at this place the causes which act more especially on the stomach. Cancer of this viscus is much more frequent in males than in females, probably owing to intemperance, and to depressing emotions of the mind, being more frequently and more permanently experienced by the male sex. Scirrhous or scirrho-carcinomatous forms of malignant disease of the stomach are seldom observed before middle age; and are most frequent in the advanced epochs of life. Hereditary predisposition, or constitutional taint, derived from a parent, has evidently a considerable influence in favouring the occurrence of the malady when other causes concur to develope it. This predisposition was remarkable in the case of the great NAPOLEON. In what this diathesis consists is not clearly shown; but the temperaments, in which it has been supposed most frequently to occur, are the nervous and lymphatic, or those mixed with the sanguine or bilious. The ranks of life in which it is most frequently observed, are the middle and higher ranks, owing probably to their greater liability to anxieties of mind, and the depressing mental emotions, which, with inanition, protracted abstinence, excessive application to study, business, &c., are the most influential causes of the malady. Protracted functional disorders of the stomach, the air and water of certain localities, the abuse of spirituous liquors, frequent or constant pressure on the gastric region, and the other causes mentioned when treating of CANCER, frequently aid profound or prolonged chagrin and anxieties of mind. Various trades, professions, and occupations have been said to favour the occurrence of the malady, but with insufficient reason, or in no very appreciable degree. (See arts. CANCER and FUNGOID DISEASE.)

90. *E.* TREATMENT.—During the commencement of cancerous affections of the stomach, there is seldom sufficient evidence of the nature of the disease to induce the physician to employ means for its arrest; and even when its nature is suspected, or correctly inferred, there is no known remedy which is capable of producing this effect. At this period, when the symptoms are chiefly those of chronic indigestion, or of chronic gastritis, the means which have been found most beneficial for these diseases, and such diet and regimen as the patient experiences the most benefit from, are also most serviceable in cancerous affections of the stomach. Even if these affections were recognised at this early period, there would be very great difficulty in devising more suitable means than those usually found most serviceable in functional disorders of the organ. If the malady be inferred to exist at this early period, or if it have more manifestly declared itself at an advanced stage, all that can be expected from treatment is—1st, to alleviate the more distressing symptoms; and, 2ndly, to retard the progress of the malady; and these ends may generally be partially attained.

91. It has been very justly remarked by M. GIBERT and adopted by Dr. HOUGHTON, that "our predecessors, who were less acquainted than we with the fatal progress of organic lesions, succeeded, perhaps, oftener than we do in palliating the symptoms and prolonging the lives of patients, by applying themselves incessantly to oppose the most obvious symptoms. Their attention was not entirely preoccupied, like that of the anatomist-physicians of the present day, with the incurability of the local lesion which is the source of the disease." But, whilst the fulfilment of the intentions proposed to ourselves when treating this malady, should be kept in view, the predisposing and exciting causes, mentioned above, and under the article CANCER, ought to be removed or counteracted by treatment, medical and regimenal, as far as may be possible. Whenever obstinate or prolonged dyspepsia, or symptoms of chronic gastritis, occur in an individual whose parent or grandparent died of this malady, then suspicions of incipient cancer of the stomach should be entertained, and the treatment ought to be directed accordingly. If these suspicions should not be confirmed, the means advisable for the more dangerous malady would not be inappropriate for the more slight; indeed they will generally prove the most rapidly beneficial.

92. There are few causes which more injuriously affect the digestive and assimilating functions than the depressing mental emotions and anxiety; and therefore these should be avoided by relinquishing avocations which involve such emotions. The greatest care ought also to be exercised in the choice of food. The patient should be guided in this by his sensations and experience; but generally the farinaceous articles of food, taken in moderate quantities, and not after too long intervals, yet in sufficient quantity to duly nourish the frame and support organic nervous power, will be found the most suitable. These may be taken in, or with, animal broths or soups, in small quantities, or with jellies, &c. I have often recommended new-laid eggs, merely warm, and asses' milk, warm from the animal, with a

small portion of lime-water, with much benefit. The great object in the treatment of inferred cases of malignant disease of the stomach is to furnish bland and unirritating nourishment in sufficient quantity, without exciting or distending the organ. But, whilst these and other articles of diet are allowed, with such others as are mentioned when treating of Indigestion (§§ 42. 55. *et seq.*), or are found by the patient to agree with him, the more painful symptoms should be allayed by suitable narcotics, or by hydrocyanic acid, prescribed in conjunction with emollients, demulcents, or mild bitter tonics. I have met with cases of inferred internal cancer, for which I have prescribed a vegetable and farinaceous diet, distilled water for all the purposes for which water is required, as advised by Dr. Lambe, and residence in a dry and mild air, and very great benefit has been derived from the treatment.

93. As to the use of the several narcotics, but little can be added to what has been stated under the head Cancer (§ 30. *et seq.*). I have preferred the more common preparations of opium, to either the acetate or muriate of morphia, in malignant disease of the stomach, the latter frequently proving injuriously depressing, without affording any countervailing advantage. The combination of narcotics, as of conium with henbane or poppy, or of opium with hop, or the infusion of hop with henbane or hydrocyanic acid, has often been serviceable. As the disease advances, the necessity of having recourse to palliative means increases, and the doses of these require also to be augmented. But it will be found that these remedies, however great the dose, frequently fail in preventing or arresting the vomiting in the advanced stages of the malady, if solely relied upon. They should, therefore, be conjoined with such stimulants and aromatics as may be found most serviceable in such circumstances, as creasote, musk, sumbul, &c. I have very rarely observed much benefit to accrue, beyond a very temporary relief, from aconite, belladonna, or stramonium. Nevertheless they may be tried in similar combinations to those just now mentioned. If acidity or flatulence of the stomach be much complained of, ammonia, magnesia, or other antacids may be given with narcotics and aromatics; or lime-water may be taken with boiled milk, or with asses' milk. The iodide of potash, in small doses, may also be tried in conjunction with the carbonate of potash, or the solution of potash, or Brandish's alkaline solution, and with narcotics and aromatics; but I have seldom seen any benefit derived from it in malignant disease of the stomach. If hæmorrhage from the stomach be indicated by black or pitchy stools, or if hæmatemesis occur, the spirits of turpentine may be prescribed in such forms or combinations as have been recommended above (§§ 59. 69. 75.), or where Hæmorrhages of these kinds are considered.

94. The constipation attending malignant diseases of the stomach often proves a great source of trouble or distress to the patient, and a great difficulty to the physician. Enemata should be daily employed; but, however active the substances which may be administered in these, they often fail of producing satisfactory results. Calomel is often too depressing, as respects the vitality of the stomach, especially when repeated, and irritating or drastic purgatives ought to be avoided. The preparations of senna or of rhubarb may be conjoined with vegetable tonics, with magnesia, or with manna, or phosphate of soda, citrate of magnesia, &c., or with such other aperients as may be found to be retained by the stomach.

95. The thirst, heat at stomach, nausea, and vomitings, which are often so distressing in the course or near the termination of the malady, can seldom be altogether allayed, although they may be sometimes partially relieved, by exhibiting effervescing beverages with bland nutrients, or mild stimulants, as Seltzer-water with milk, and a small quantity of weak wine, as hock, Barsac, &c.; or soda-water, or effervescing lime-water, with the same articles; or spruce-beer, or small quantities of weak tar-water, with milk, &c.; and by making these the vehicles in which the medicines most appropriate to the case may be given. The retchings and vomitings are sometimes relieved by combining creasote with opium and cretaceous powders or mixtures; and epithems, with the vinum opii, or with one or other of the warm embrocations prescribed above (§ 59.), to which the opiate is added, may be applied over the epigastrium. If diarrhœa, or extreme vital depression, or spasms, supervene, these means, aided by the more powerful stimulants, absorbents, and astringents, may be administered; but no further advantage than a temporary relief can be expected from them.

96. iv. Other Organic Lesions of the Stomach are occasionally observed, but they can rarely be distinguished during life; and, when met with upon dissection, the only particulars which can generally be obtained as to their origin and the symptoms attending them, are such as usually accompany chronic gastritis, or scirrhous or malignant diseases of the organ. These lesions have been fully described in the article Digestive Canal (§§ 27. *et seq.*); and to that I beg to refer the reader. — *A.* Those alterations which are most frequently observed, are generally consequent upon prolonged irritation, and upon excesses in eating and drinking, and consist chiefly of *hypertrophy of the villous and muscular coats and of the connecting cellular tissue*, existing either singly or in combination. They may not be attended by any serious symptom, and be detected only after death from some other disease. When, however, they are seated in either the cardiac or pyloric orifices of the organ, and are attended by much thickening of the part, they occasion more or less disorder, according to the amount of obstruction they produce; and in such circumstances they may be mistaken for, although different from, malignant disease of the viscus. It is very rarely that very serious symptoms are occasioned by these alterations, unless ulceration supervene in some part of the thickened or hypertrophied structure; and in such cases, it is very difficult to determine whether or no the alteration be truly scirrhous, which it most probably often is, if the hypertrophy or thickening be chiefly seated in the submucous cellular tissue.

97. In these cases, whether they result merely from prolonged irritation, excitement, or inflammatory action, or whether they be incipient cancer, the *treatment* should not be materially different from that which has been advised for other diseases of the stomach, namely, to improve the general health, to promote the constitutional powers, and to remove or to relieve

the symptoms which are either most important or most urgent. With these intentions, change of air, travelling, the use of mineral springs, or waters suited to the symptoms most complained of, and attention to diet and regimen, should be recommended.

98. B. *Alterations of the Capacity of the Stomach* are sometimes observed (see Digestive Canal, § 52. *et seq.*).— a. *Increased capacity* is generally a consequence of more or less obstruction at the pyloric orifice or its vicinity. In cases of scirrhous or cancerous pylorus, the stomach is often remarkably increased in capacity; and when the pylorus or upper portion of the duodenum is constricted from other alterations, increased capacity of the viscus is also generally observed. In a case in which inflammation of the concave surface of the liver extended to the pylorus and head of the duodenum, and was followed by false membranes and adhesions of these parts, the subsequent organization and contraction of the morbid productions had so completely constricted the pylorus, as to prevent the passage of a quill through it; the patient having died under my care with symptoms, which were referred to scirrhous pylorus, and with enormous dilatation of the stomach. In some cases, the increase of capacity is attended by hypertrophy of the muscular and villous coats; but this is observed only in some of the more chronic cases of scirrhus of this orifice. In others, the increased capacity is attended by remarkable thinness of the coats. Greatly enlarged capacity of the organ, with hypertrophy of the coats, has been observed in some cases in which habitual gluttony had existed during life. In such instances, increased function or action had developed the growth of the structures and the size of the organ.

99. b. *Diminished capacity* of the stomach is also sometimes seen (see Digestive Canal, § 53.), but most frequently in consequence of inanition, or in connection with hypertrophy of the coats, or with scirrhous or other malignant diseases of the organ. It may be occasioned also, although very rarely, by the cicatrization of ulcers, or by the contraction of false membranes, or of organizable lymph thrown out upon the serous surface of the organ. Extreme diminution of capacity is caused by the passage of acrid, corrosive, or astringent poisons into the stomach, especially the mineral acids; and is then not infrequently attended by abrasions of the villous coat. Kiernander observed it after poisoning by nux vomica.

100. C. *Attenuation of the gastric tissues* is not often observed without any other change. It is most frequently seen in cases of obstruction of the pylorus, and then is often associated with increased capacity, especially at or near the fundus of the organ. But it is met with, also, without any increase of size. Several other alterations of structure have been found in the stomach, namely, *anomalous fibrous and fibro-cartilaginous formations, tubercular ulcerations, fatty or lipatomatous tumours in the connecting cellular tissue, fistulous openings through the coats of the stomach and parietes of the abdomen, or some other part of the digestive canal, and various displacements of the organ*, &c. But these are of very rare occurrence, and seldom admit of diagnosis or of relief during life. (See arts. Digestive Canal; Cancer; Disease, &c.)

101 .D. *Rupture or laceration* of the coats of the stomach has been observed after vomiting or retchings in the course of disease or of ulceration, especially when the coats have been attenuated or softened in parts, or where ulceration has penetrated the muscular coats, and nearly or altogether reached the peritoneal surface. The same result has followed from distension of the viscus by ingesta, or more probably from the reaction of the parietes upon the distension. Rupture of the stomach is not infrequent after falls, or violent blows on the region of the stomach, especially when distended by a full meal.

102. E. *Wounds* penetrating the walls of the organ are generally fatal; but in some instances recovery has taken place from them, either with or without a fistulous opening in the abdominal parietes. Whilst lacerations are always fatal, wounds may fail of proving fatal, the coats contracting so as to prevent the passage of the contents of the viscus into the peritoneal cavity, and closing up and ultimately cicatrizing; or if continuing open or fistulous, the lymph exuded around the wounded peritoneal surfaces agglutinating them, and preventing the consequences observed in other circumstances.

103. F. *Numerous foreign bodies*, which have been swallowed, may be retained for prolonged periods in the stomach, and produce various effects according to their natures or their chemical or mechanical properties or conditions. They may irritate, inflame, ulcerate, or even perforate the viscus. The irritation may be soon followed by their rejection. Even blood, effused from ulcerated parts, or diseased vessels, of the organ, or that which has passed into it from the nares, fauces, or pharynx, when present in considerable quantity, will be thrown off; but, when it is present only in small quantity, it will pass the pylorus into the intestines, and give the stools the characters of melæna. Cases on record are numerous in which foreign bodies have been retained for weeks and even months in the stomach, and either have been afterwards thrown up, or found there on dissection, or have caused ulceration and perforation, not only of the stomach, but sometimes also of the adjoining viscera or parts.

STOMATITIS.—Synon. *Stomatitis* (from *στόμα*, the mouth). *Stomacace, Oris Vitium, Buccitis. Buccite, Stomatite, Inflammation de la Bouche*, Fr. *Inflammation of the Mouth.*

Classif.—III. Class. I. Order (*Author in preface*).

1. Defin.—*Inflammation affecting the mouth, especially the gums and cheeks, attended by more or less constitutional disturbance, and characterised, as respects the local changes, by the nature of this disturbance, by the causes, and by the state of vital power.*

2. Inflammation of the mouth, or stomatitis, may be either a primary or a secondary or sympathetic affection. It is rarely limited to the gums and cheeks; but extends, more or less, in most of its forms, to the fauces and pharynx, and even partially to the tongue and lips. According to the sthenic or asthenic character of the inflammation, — to the local changes and the constitutional disturbance,—to a previously healthy, or to a cachectic or contaminated state of the system, — and to the influence of the exciting causes, stomatitis presents several *species*, more or less distinct, and hence deserving of being treated of as specific affections, yet, owing to their seat, and not infrequently to their consequences, requiring to be viewed as generically related to each other. The several affections which may be classed under the present head appear, either primarily or consecutively, under so different circumstances, that it may be truly stated that there are few diseases affecting the same parts so dissimilar to each other as these are. This dissimilarity, arising, as just stated, from the different exciting causes of each, from the states of vital power and of the circulating fluids, from the nature of pre-existing disease, and from the age and various other circumstances of the patient, gives occasion for the arrangement of the several forms of stomatitis into the following *species*: — 1st, simple or erythematic, *stomatitis simplex*; 2d, vesicular, *st. vesiculosa*; 3d, pultaceous, *st. pultacea*; 4th, mercurial, *st. mercurialis*; 5th, pseudo-membranous, *st. pseudo-membranacea*; 6th, ulcerated, *st. ulcerata*; 7th, gangrenous or phagedenic, *st. phagedænica*. The *second* and the *third* of these *species* I shall describe under the head Thrush, the term usually applied to them; the others will be briefly treated of at this place.

3. I. Stomatitis Simplex, *simple or erythematic inflammation of the mouth,— Buccite, Aphthes érythématiques,*—is characterised by redness, heat, dryness, pain, and slight swelling, of a part or of the whole of the mucous membrane lining the mouth. It is most frequently limited to either the arch of the palate, to the tongue, to the gums, or to the cheeks. It is often extended to two or more of these, but it more rarely invades the whole of the buccal surface. It frequently extends backwards to the isthmus of the fauces, to the pharynx, and even to the upper part of the œsophagus. It is not an infrequent complication of gastritis, or gastro-enteritis, or of bronchitis, and is generally more or less remarkable in the exanthematic fevers, and in an advanced stage of hectic. When the inflammation has followed a local irritant or poisonous substance, then the pain, heat, and swelling are often very severe, and the effect more diffused. In some instances the inflammation is attended by dryness, in others by a discharge of a ropy mucus, mixed with saliva, more or less abundant, according to the nature of the exciting cause. Occasionally the irritation extends along the Eustachian tube to the ear; and in many instances the tonsils are more or less affected.

4. *A.* Simple stomatitis thus presents numerous phases or states, as it is more or less general or limited, or according to its severity, to its complications, to the age of the patient, and more particularly to its cause. It may be general or diffused, or limited to patches, or to parts, or consisting of numerous points. It may or may not be attended by the symptoms of general fever, which usually assumes either an asthenic or sthenic character, according to the severity of the attack and the constitutional power of the patient. It generally presents acute features, and terminates in a few days, by resolution, without either suppuration or ulceration, the epithelium being commonly detached. But suppuration is occasionally produced when the inflammation has been intensely excited by an energetic irritant poison, or even by the more common irritants in unusual quantities. I have thus seen a very general stomatitis, with profuse suppuration, follow the introduction of a quantity of mustard into the mouth. Ulceration is more frequent than suppuration, and is seen chiefly in the gums, insides of the cheeks, and on the surface of the tonsils. Generally, however, the inflammation has become chronic before ulceration to any considerable extent takes place.

5. *B.* The *chronic state* of simple stomatitis is chiefly confined to the gums, and is often kept up by carious teeth or stumps of teeth. In the worst of such cases the gums not only ulcerate, but the alveolar processes, either partially or more generally, become absorbed, and the teeth fall out. These cases are commonly symptomatic of general cachexia, or of prolonged disorder of the digestive organs, especially chronic dyspepsia or chronic gastritis.

6. *C.* The *treatment* of simple stomatitis is generally easy, when the affection is produced by a manifest irritant cause; for the removal of this cause, and rinsing the mouth frequently with cooling and demulcent fluids, will be efficacious in the course of a few days. When this affection is a part only of a more general and a more serious complaint, the local means can be subservient only to more constitutional and energetic remedies, and these must be such as the nature of the complaint will warrant. The state of the alimentary canal and of the digestive organs should receive particular attention, and morbid secretions and excretions, and fæcal accumulations, be freely evacuated. In many cases, washing out the mouth with camphor water, or with a decoction of marshmallows, containing a little nitrate of potash or sulphate of alumina, or, in more painful cases, holding the open mouth over the vapour of hot water, into which some vinegar and scraped camphor has been put, will be sufficient to remove the disorder, especially when aided by suitable purgatives. In more chronic and obstinate cases, especially if ulceration have taken place, strong solutions of the nitrate of silver, or weak solutions of the bichloride of mercury, may be required. Most of these states of the disorder, even when unconnected with secondary syphilitic disease,

depend upon cachexia and chronic disorder of the digestive organs; and to these latter the treatment should be mainly directed. For these obstinate and complicated states, the means about to be prescribed for a severer variety of this complaint will be found appropriate (see §§ 31. *et seq*).

7. II. PSEUDO-MEMBRANOUS STOMATITIS.—*Stom. Pseudo-membranacea.*—*Stomatite Couenneuse, St. Dipthéritique, Dipthérite Buccale*, Fr.—This peculiar form of stomatitis, as it affects either the mouth or throat only, or as it extends not only to both, but also to the pharynx, larynx, and even to either the trachea or œsophagus, was first accurately described by M. BRETONNEAU, and subsequently by M. TROUSSEAU and Dr. MACKENZIE, by whom it was observed to occur in an epidemic form. In some districts of France, especially the more extended or diffused state, it was on several occasions a remarkably prevalent and fatal malady, and was considered by the best informed writers to have been propagated by infection. This very severe and epidemic form of *angina* will receive due attention when the diseases affecting the THROAT are described. I shall, therefore, notice at this place only the less severe and limited form of the malady, which affects the mouth primarily, and is most frequently confined to this part.

8. *A. Pseudo-membranous stomatitis* has been confounded with various other affections of the mouth. It may assume either an *acute* or a *chronic* form; and is generally more or less diffused when acute, and limited to one part when it assumes the latter form. It is observed chiefly on the gums, insides of the cheeks and lips, and on the point or around the tongue. In the *acute state* it first appears in the interior of the mouth in the form of small, irregular, rounded or oblong membranous patches of a greyish-white colour. Around these patches the surface is red, and the parts are painful and hot, a sense of heat or burning being complained of. The breath is fœtid, and the submaxillary glands enlarge. As the disease proceeds, the patches of membranous exudation extend, become more or less detached, and are succeeded by others, and the intervening surfaces are red and swollen. The tongue is swollen. The mouth is continually open, allowing the escape of altered saliva. The enlargement of the lymphatic glands increases; the face swells; the breath becomes more fœtid; and the pulse more quick or rapid, and generally soft, open, and full, or weak. With the increasing severity of the accompanying fever, the disease extends to the throat, and even to the respiratory and digestive mucous surfaces, thereby occasioning great or very imminent danger.

9. This form of stomatitis may be confounded with the THRUSH, or with *mercurial stomatitis*, from which latter it may be distinguished by absence of the cause, and of the mercurial fœtor of the breath. It is more closely allied to the thrush, from which it differs chiefly in the larger patches of exudation at the commencement of the disease, in the more rapid and continuous extension of these patches, in the greater amount of fever and of swelling of the adjoining parts, and in the more advanced age of the children most frequently attacked, the thrush occurring generally, or oftenest, in much younger children than this form of stomatitis, commonly in infants during, or soon after, lactation.

10. Pseudo-membranous stomatitis may terminate in resolution, the swelling and redness diminishing, and the membranous exudations being either detached or absorbed; or it may pass into the chronic state; or it may go on to ulceration, or even to gangrene. The first of these terminations is the most frequent, the parts healing without leaving any cicatrix. But the affection is not infrequently chronic, usually after a more or less acute state. In the acute form, it often extends to the pharynx and respiratory passages, and sometimes also to the digestive mucous surface; and, when thus complicated, it generally terminates fatally. In the chronic state, it is usually limited to the mouth; and may continue for several weeks or even months.

11. Relapses are frequently observed in weak cachectic children, especially when confined in an unwholesome air, or crowded apartment. M. GUERSENT states that the cases of this complaint in the hospital for children in Paris are very subject to relapses.

12. *B.* The *causes* of pseudo-membranous stomatitis, are chiefly those which lower the constitutional powers, and impair the assimilating functions. This complaint may occur at any age, but it is most frequent during the second dentition, and during the evolution of the molar teeth. It is very rare during lactation, but becomes more frequent from the first year of age, until the second dentition is completed. It is observed chiefly in autumn and winter; and in these seasons especially, and not infrequently also in the spring, it is almost endemic in some countries, whose climates are cold and humid, and in districts subject to inundations. In these particularly it may even become epidemic.

13. The *predisposing causes* are whatever impairs the general health, as impure air, unwholesome food, insufficient clothing, and want of cleanliness; living in cold, low, and humid cellars; crowded apartments and sleeping-places; want of exercise in the open air; and privation of light and sunshine and of due ventilation. M. GUERSENT states that this form of stomatitis is almost endemic in the hospital for children in Paris, especially in the wards appropriated to ophthalmic, cutaneous, and scrofulous affections; and that boys are more affected than girls. It has been supposed to have been propagated by contagion, in circumstances favourable to this mode of communication; but the evidence of the possession of this property by this affection is not always conclusive, although cases have appeared to warrant a belief in the existence of it, especially when the disease is prevalent.

14. *C. Treatment.*—VAN SWIETEN advised the application of the hydrochloric acid in a proportion of honey, varying with the severity of the case (from one-fourth or one third to three-fourths of the former), by means of a small piece of sponge attached to a small stick, to the membranous exudations. But care should be taken that this application should extend as far as the exudation. Generally one or two applications in the twenty-four hours are sufficient. At the same time a terebinthinate embrocation, such as No. 296. or No. 311. in the *Appendix*, should be applied by means of flannel or spongeo-piline around the throat, or along the sides of the lower jaw. After a few applications of the acid and honey, or, in the intervals between the application of them, a

gargle or wash, consisting of the decoction of cinchona and hydrochloric acid, or any other astringent gargle, may be employed. In some cases I have found a varying proportion of borax and honey efficacious; and when the patients have been old enough to use a gargle, then a saturated solution of borax, in any suitable vehicle, has also been used. A strong solution of alum, or alum in fine powder, with acacia-powder or mucilage, has also been recommended by BRETONNEAU and others; whilst the nitrate of silver, in various states of solution, or even in substance, has been advised by many. More recently, the chlorides, especially the chloride of lime and the chloride of zinc, in varying grades of solution, according to the severity of the disease, or in the state of powder conjoined with other substances, have been severally prescribed by myself and others.

15. If the disease have advanced to simple or to phagedenic ulceration, the above means should be employed in more energetic or concentrated forms; and such other means should be used as will support the vital powers and resistance, and thereby change the morbid action locally. In all cases, indeed, but in these especially, internal and constitutional means ought to be appropriately prescribed. Some writers have advised the application of leeches to the throat or neck, &c. I have often been called to patients after recourse has been had to them, but I have rarely seen much benefit derived from them. I would not say that they should not be applied in the more sthenic cases, or in robust or plethoric patients; but these latter are rarely attacked by the disease; and, when they are, the employment of leeches for them is likely to be of service, especially when the applications to the mouth and the embrocations to the throat and neck, advised above (§§ 14.), are also duly resorted to. In most cases, the preparations of cinchona, with ammonia, or with the fixed alkalies, or with diaphoretics, as the liquor ammoniæ acetatis and spiritus ætheris nitrici, are beneficial, especially when the pulse is quick and soft, and the flesh is flabby or soft. In some it will be requisite to administer the most powerful tonics and stimulants, as the preparations of cinchona with hydrochloric acid and hydrochloric æther, tincture of serpentaria, &c.; and even to allow a sufficient quantity of wine in arrow-root or sago. The bowels should be freely opened by the usual means, or by equal quantities of castor oil and oil of turpentine, administered by the mouth, or in enemata, or in both ways, according to the urgency of the case. If the disease assume *a chronic form*, internal or constitutional means are always required; and of these means, change of air, especially to a warm and dry locality, is one of the most important and successful, especially when aided by an appropriate use of one or more of the remedies already noticed.

16. III. STOMATITIS MERCURIALIS — *Mercurial stomatitis* is one of the more common forms in which the poisonous effects of mercurials manifest themselves. It has, therefore, been described, and fully treated of, in connection with other injurious effects of mercury, in the article POISONS, from §§ 562. to 594. inclusive; §§ 568. 580—587. and 593., more particularly relating to mercurial stomatitis.

17. IV. STOMATITIS ULCERATA — *Ulcerated Stomatitis—Cancrum Oris* — may be an advanced stage of either simple stomatitis or of pseudo-membranous stomatitis. — *A*. It may also commence with inflammation of the external surface of one or more of the gums, most frequently of the lower jaw, and generally on both sides. With the inflammation, swelling and œdema are often very considerable; ulceration soon appearing over the alveolæ and near the teeth. The cheeks and face are swollen; the sub-maxillary glands are tumefied; the mouth is opened with great difficulty; and saliva with mucus fills the mouth, and prevents a satisfactory view of the diseased surface. A coppery, unpleasant taste is complained of, and a peculiar fœtor of the breath is remarked. Heat, tenderness, and swelling of the face increase, and ulceration extends over the gum, sometimes exposing the alveolar processes, and often to the cheeks, if the disease be not early checked. It may be stationary for some days, especially when partially controlled by treatment. In some cases more or less hæmorrhage takes place from the ulcerated parts. The febrile symptoms are generally of an asthenic or low character; the pulse being soft, weak, frequent, or small; and the skin cool or natural, excepting that of the face and neck; and the bowels confined or irregular.

18. This form of stomatitis is most frequently seen in children between the first and second dentition, after weaning, and during recovery from exanthematous fevers, especially from scarlet fever. It generally occurs in cachectic and debilitated subjects, and in the children of the poor, that are ill-fed, and live in low, close, and crowded and ill-ventilated apartments. It is not infrequently superinduced by disorders of the stomach and bowels, and should be viewed as a very serious malady, especially when it appears in the circumstances now mentioned, and more particularly when it occurs after scarlet-fever; the prognosis, however, should depend chiefly on the constitutional symptoms, especially when these are correctly interpreted, and upon the absence or presence of visceral complications.

19. *B*. A *variety* of ulcerative stomatitis sometimes occurs in adults, consecutively upon exhausting discharges, and as a sequela of other diseases. It occasionally appears in delicate females during lactation, and in the course of debility, or of debility conjoined with cachexia, produced by other depressing or exhausting causes. The disease in these cases usually commences with inflammation of one, seldom of both, sides of the tongue, and extends to the inside of the cheek. In some cases, one or more very small, hard, and painful sores first appear on the side of the tongue, which ulcerate, with hard and elevated margins, and are followed by a more extended inflammation; and in others these ulcers supervene upon previously existing inflammation. As the disease proceeds, the interior of the mouth appears red and inflamed, is very painful, and so tender, that fluids only, and these of the blandest kind, can be received into it. The tongue is red, smooth, or glossy, and a copious flow of saliva takes place from the mouth. There is at first neither loss of appetite nor fever; but as the affection extends over the internal surface of the mouth, cheeks, and tongue,

fever supervenes, and the stomach and bowels become irritable, the morbid irritation extending to the pharynx and along the œsophagus to the stomach and bowels; diarrhœa, emaciation, and extreme exhaustion, sometimes supervening, and even terminating in death. Drs. Hale, Backus, Wilson, and Holt, of the United States, have described this variety of stomatitis, and state that it occurs chiefly in women when suckling, or in an advanced stage of pregnancy. But it is not peculiar to them, cases of it occurring, on rare occasions, in the circumstances already stated, especially when debility is associated with more or less visceral disease.

20. *C.* The *Treatment* of ulcerated stomatitis should be mainly constitutional, means being used to improve the vital powers of resistance, and to prevent the extension of the local changes. The states of the excretions should be carefully ascertained, especially of the urine, and the treatment directed accordingly. In some cases, the treatment is beneficially commenced with an emetic of sulphate of zinc; and a purgative powder or draught, suitable to the state of the bowels and appearances of the stools, is often afterwards required. The decoction of cinchona, with muriatic acid, and muriatic æther, or with the nitro-muriatic acids, or with ammonia or the fixed alkalies, according to the state of the urine, is always more or less of service. It may be necessary to have recourse to wine in addition to these or other tonics, or to the sulphate of quinine given in the compound infusion of roses, &c. The bowels should receive due attention during the progress of the case; and the occasional administration of an enema containing oleum terebinthinæ will generally be of service, as respects not merely the state of the bowels, but also the system generally.

21. The local affection has too commonly been viewed as local merely — as simply inflammatory; and the inflammation has too frequently been considered as of an ordinary sthenic kind, instead of asthenic, and requiring very opposite means to those often employed. Because there have been swelling, increased redness, enlargement or engorgement of the adjoining glands, leeches have often been prescribed, and have either increased the mischief or have had no beneficial influence on the disease. Cold applications to the neck or the throat have not been of greater service. I have generally employed, with benefit, embrocations to these situations, consisting chiefly of the terebinthinated and camphorated forms prescribed in various parts of this work, and in the *Appendix*; and such applications or gargles to the affected parts, as the age and circumstances of the case suggested. When the patient can use a gargle, then the decoction of cinchona, with hydrochloric acid, or with hydrochlorate of ammonia, or with alum, or with tincture of myrrh, or of krameria: or strong tar-water; or various fluids containing creasote, or even the chloride of zinc, or of lime, in small quantities, may be severally tried, according to the peculiarities of the case, and the effects produced.

22. Washes, lotions, linctuses, &c., are likewise of great service, especially when the former are applied directly to the parts by means of a sponge attached to a small stick or piece of whalebone. Washes or lotions may contain either the nitrate of silver, or the sulphate of zinc, or the chloride of lime, or the chloride of zinc. When a linctus is preferred, then the substance should be such as may be passed into the stomach not only without danger, but with benefit. Thus a linctus may be prescribed, containing either the hydrochloric acid, or the oleum terebinthinæ, or the tincture of cinchona or of myrrh, or red wine, &c.; and when an emetic effect is desired, then the sulphate of zinc may be given in this way.

23. The *variety* of ulcerated stomatitis described by the American physicians as peculiar to pregnant and puerperal females requires also a restorative and tonic treatment. Dr. Backus advises, as local applications, mild astringent infusions, or a solution of nitrate of silver. Suckling in these cases ought always to be relinquished. Dr. Holt states that the disease has invariably yielded to iodide of potassium, given in doses of five grains three times a day, a cure having been obtained in a very few days, often in two or three. Dr. Wilcox says that he has met with uniform success from the decoction of *Polygonum punctatum* of Elliot, made by boiling an ounce of the dried leaves and tops in a pint of water for twenty minutes, and employed as a gargle almost hourly.

24. V. Stomatitis Phagedenica. — Synon. —*Cancrum Oris—Cancer Aquaticus—Stomacace Maligna — Noma — Gangrenous Stomatitis — Water-Canker—Sloughing Phagedena of the Mouth.*— This most dangerous and very often fatal affection presents, from the commencement, very different characters from those of the other forms of stomatitis. The gangrene or sloughing which occurs consecutively of the forms of stomatitis already noticed is merely an occasional termination of these, owing either to neglect, or to general cachexia, or to extreme exhaustion or depression of vital power: but this malady is primarily and idiopathically distinct from the gangrena oris — from the gangrenous terminations of the other kinds of stomatitis.

25. *A.* The *literary history* of phagedenic stomatitis is briefly as follows. The disease appears to have been noticed by C. Battus, a physician in Amsterdam, as early as 1620; and Vander Woorde soon afterwards designated it by the term *water-kanker.* Arnold Boot in 1649 described it by the names of *labrosulcium* and *cheilocace*, very probably confounding it with other forms of stomatitis. Van Ringh assigned it the name of *scorbutic cancer;* and Van Lill called it *noma, ulcus noma*, and *stomacace.* Callisen designated this malady *stomacace gangrenosa;* Lentin, *ulocace*, and Wendt, *sphacelus of the mouth.* Lund, a Swedish physician, saw eleven children with this malady, which he named *noma*, and of these ten died. Meza described it as he observed it in Denmark. Drs. Coates and Jackson met with it in the United States, the former calling it *gangrenous ulcer* of the mouth, the latter, *gangagræpsis;* but they probably did not distinguish between it and other forms of stomatitis. It has also been noticed by C. F. Fisher, Siebert, C. G. Hesse, Rust, Schmalz, Hildenbrand, Girtanner, Joerg, Reimann, Weigand, Hueter, &c. The most detailed accounts of the disease have been furnished by A. L. Richter, Guersent, Blache, Taupin, Rilliet and Barthez. The first of these has described three varieties of

this malady — 1st, the *noma scorbutica;* 2ndly, the *noma metastatica;* and 3dly, the *noma gastrica* — divisions which are more imaginary than real. The two last of these writers have adduced twenty-one cases of the disease; and, as well as M. Guersent, have appropriated much of what has been advanced by Richter. M. Taupin has described thirty-six fatal cases which occurred in the hospital for children in Paris.

26. *B.* The *symptoms* of phagedenic stomatitis are commonly swelling and hardness of one cheek or lip, — of the cheek most frequently, — without marked increase of heat or redness, and without much tenderness or pain, even on examination. Owing to the absence of acute or active symptoms at the commencement, the disease is often overlooked at first, or until it has made a dangerous progress. The tumefaction externally is, however, early attended by a waxy and glossy appearance, which is so characteristic as to direct the instant attention of the physician to the disease, although it may have been overlooked or unattended to by the friends of the patient. On examining the mouth little or no redness or mark of inflammation is observed; but, in the internal surface of the swollen part, an ash-coloured or whitish eschar or slough of small size may be detected in the centre of the cheek, or in the commissure of the cheek and lower jaw, surrounded by hardness and swelling. The tongue is pale, flabby, or slightly loaded; the gums are pale and spongy. There are more or less marked indications of debility, exhaustion, and cachexia, with languor and fretfulness. The pulse is generally small, soft, and quick; but without much increase of temperature, until towards evening. The evacuations are unhealthy and offensive.

27. If the disease come under treatment at this early stage, a judicious treatment will frequently arrest its progress. But, as it advances from this stage, the danger increases. The slough or eschar on the inside of the cheek soon spreads, and even extends to the lips and gums; and is attended by a copious discharge of saliva, which is clear at first, but soon becomes turbid and mixed with mucus and a sanious matter. The breath is now very offensive. As the gangrenous disorganisation thus extends, the external appearances indicate the invasion of the integuments about the centre of the tumefaction. A vesicle or a pale or ashy spot appears in this situation, and soon becomes livid and sloughs. The discharge from the diseased parts is now remarkably contaminating and corroding, the lower lip, the angles of the mouth, and the alveolar processes, being not infrequently destroyed by it. The teeth often fall out, with dead portions of the alveolæ; and, if death does not previously occur, both sides of the face may become affected, or the gangrene may extend to all the soft parts of the mouth and face, and even to the maxillary, the palatal, and the nasal bones.

28. As the malady thus proceeds locally, the constitutional symptoms are chiefly those of increasing vital depression and contamination of the circulating fluids. The cachectic indications are more and more apparent; the pulse more rapid, feeble, and small; and the bowels, which at first were confined, generally become much relaxed and extremely offensive. The urine is offensive, alkaline or phosphatic, or soon becomes ammoniacal. The general surface is usually cool; the extremities become cold; and life gradually, but quickly, ceases. From an early period, the disease may be *complicated* with more or less internal disease, more especially with latent or congestive pneumonia, or with an asthenic gastro-enteritis; but these are only contingent or occasional associations.

29. *C.* The *diagnosis* of phagedenic stomatitis is, from the commencement, sufficiently evident. The hard, indolent swelling, and the peculiar glossy or waxy appearance of its outer surface, and the small slough in its internal surface, are quite characteristic of this malady.—The *prognosis* should be unfavourable or stated with great caution from the first. If the disease be seen at the early or œdematous stage, and be treated in, or can be removed to, a wholesome situation, a judicious treatment may arrest its progress; but if gangrene be established, although recovery may take place, disfigurement cannot be prevented; and if sloughing and the constitutional symptoms have advanced and are severe, recovery cannot be expected. When the disease appears in hospitals for children the issue is generally fatal.

30. *D.* The *causes* of phagedenic or gangrenous stomatitis are those already noticed, as occasioning the other forms of stomatitis, more especially pre-existent cachexia, depression of vital power, or exhaustion by previous disease, by exanthematous fevers, by protracted disorder of the pulmonary, the digestive, and assimilating organs, and by living on unwholesome and insufficient food. Low, cold, and humid apartments, particularly cellars, ground floors, &c., are also not infrequent concurrent causes of the disease. The specific action of mercury may favour or more directly occasion it, although it more frequently appears independently of this mineral, and when none of its preparations have been taken. It occurs chiefly between the ages of two and nine years, but most frequently from three to six years of age. The air of hospitals for children is most commonly productive of this malady; and, when treated in the wards of these hospitals, recovery rarely takes place. M. Taupin has seen thirty-six cases in the hospital for children in Paris, and they were all fatal.

31. *E. Treatment.*—Prompt and decided measures are required for this form of stomatitis. The patient should be removed into a dry, warm, and well-ventilated apartment, and the causes of the disease as far as possible avoided. The state of the cheeks and mouth should be very carefully ascertained, and means appropriate to the existing changes instantly applied. If no slough have as yet appeared in the interior of the cheek, the terebinthinate embrocation (§§ 14. 21.) should be applied externally, and the internal surface be washed by a lotion of strong tar-water. If the latter cannot be readily obtained, one part of oleum terebinthinæ ought to be mixed in three of honey, and applied to the inside of the cheek and gums twice or thrice daily. In some cases I have given a warm stimulating emetic of sulphate of zinc, and a small quantity of capsicum, with marked advantage, and subsequently a stomachic aperient draught, the operation on the bowels having been promoted by a terebinthinate enema. During the treatment of the early stage of the malady, the decoction of cinchona, with muri-

atic acid and æther, or with ammonia, or with chlorate of potash, or the quinine or other tonics, as advised above (§§ 20.), should be given at duly regulated periods, between the administration of suitable nourishment.

32. In a further advanced stage, when a slough has become very manifest in the mouth or cheek, the part ought to have solid nitrate of silver, or strong hydrochloric acid, applied to it, the surface being frequently washed by the lotions already mentioned, or by a strong solution of nitrate of silver, or muriate of ammonia, or with washes containing the chloride of lime, or of zinc, or creasote, with camphor and myrrh. These latter will tend to arrest the sloughing, will correct the fœtor, and will counteract the contaminating influence of the discharge from the diseased part. During this period, cinchona and other tonics, in combinations already mentioned, should be prescribed; and beef tea, with rusks; the yolks of eggs, with wine or brandy; turtle soup, and other nourishing, digestible, and restorative articles ought to be freely supplied. Instead of wine, or in addition to it, in the more extreme cases, the mistura spiritus vini Gallici may be administered in doses suitable to the age of the patient. From 1821 until 1825 or 1826 I frequently had recourse to the chlorate of potash in this and in other asthenic diseases, at the Infirmary for Children. But I seldom found it of great service when given alone at advanced stages of these maladies. It was, however, often prescribed in conjunction with other remedies, with much benefit, and especially in the forms stated in early parts of this work— with the decoction and compound tincture of cinchona, or with cascarilla, camphor, &c.

33. When sloughing has made still further progress, the local means already advised ought to be more frequently employed, and in more concentrated forms. Turpentine mixed with honey, in equal quantities, or thickened with liquorice powder, should be applied to the part, and if the external surface of the swelling become livid, the same application ought to be made to it; or an incision should be made into it, and the incised part frequently injected with either of the lotions or washes already mentioned. MM. BARON, BILLARD, and others, have recommended the actual cautery, at a white heat, to be applied to the incised part. Of this last I have no experience and little hope. The other means I have found successful when the constitutional powers have been duly supported, and when the disease had not advanced to a hopeless condition before medical aid was obtained. When great irritability and distress have appeared in cases of this malady, I have generally conjoined some preparation of opium with the local means, and prescribed it internally with camphor and other remedies, having due regard to the age of the patient, and directing it with much caution at an early age.

SUCCESSION. — SYNON. — *Succussio;* — *Secousse, Succussion*, Fr.; — *das Schütteln, die Orschütteln*, Germ.; — *Hippocratic Succussion of the Trunk.*

CLASSIF.: — GENERAL PATHOLOGY — SEMEIOLOGY.

1. *Succussion of the trunk* of the body was mentioned by HIPPOCRATES in several parts of his works, and was employed by him to ascertain the presence of purulent and other fluids in the cavities of the chest. MORGAGNI, in noticing this mode of diagnosis, admitted its frequent failure, but in such a way as evinced his ignorance of the circumstances to which failure is owing. LAENNEC first clearly demonstrated the conditions upon which the evidence furnished by succussion depends, and since his time this mode of investigating diseases of the chest has been resorted to whenever they have been supposed to have been attended by effusion of fluid into the thoracic cavities. It is chiefly in *pneumathorax* that succusion produces the *sound of fluctuation* in the pleural cavity, for it is necessary to the production of this sound that, along with the fluid, more or less air should also be present.

2. *Succussion* is performed, as recommended by HIPPOCRATES, by seizing both shoulders of the patient, whilst he is seated, and, having applied the ear to the side of the thorax, by jerking the trunk, or by abruptly turning or shaking the trunk, a sound resembling the splashing or fluctuation of water is then heard, if a fluid and air be contained in the cavity. If the cavity contain no air, although filled by a liquid, no sound will be produced, for the collision of the fluid with air is requisite to the production of sound, and the greater the quantity of air the more distinct will be the sound of fluctuation or splashing. Care should be taken, during this mode of investigation, to distinguish between the sound of fluctuation produced by succussion in the stomach, when this organ contains much air and liquid, and that which is produced in one of the thoracic cavities. A mistake will be prevented by the slightest attention, for the seat of fluctuation is generally easily manifested. In many cases, the patient

himself can perform succussion; and it is often useful to cause him to perform it whilst the physician applies his ear to the presumed seat of effusion. Succussion is useful chiefly in the diagnosis of pneumo-hydrothorax or pneumathorax. (See art. PNEUMATHORAX, § 17.)

SYCOSIS. — SYNON. — *Sycoma; Sycon, Sycosis (from σνκον, a fig);—Mentagra;—Ficus;—Sycosis menti;—S. barbæ;—Mentigo;—Varus Mentagra;—Phyma Sycosis;—Roseola ficosa;— Dartre pustuleuse mentagre,* Fr. — *Barber's Itch;— Chinwelk;—Whelk.*

CLASSIF.—IV. CLASS, IV. ORDER (*Author*, in *Preface*).

1. DEFIN.—*A chronic pustular eruption, either scattered singly, or clustered, over the chin, upper lip, or lateral parts of the face; the pustules being pointed and seated chiefly in the hair-follicles and connected tissues, and being sometimes propagated by contagion.* (See art. SKIN, § 78.)

2. i. DESCRIPTION.—This chronic eruption of the skin appears chiefly on the hairy parts of the face; and sometimes on the nape of the neck, and much resembles acne. It seems to be developed in the hair-follicles and sebaceous glands, and their connected tissues, giving rise to conical elevations, which become pustular. The pustules are generally traversed by the shaft of a hair; are of a pale yellow colour. Their evolution is usually attended by a sense of heat and tension of the affected parts. When *disseminated* they appear as very small red points, which gradually become more prominent, until about the third day, when their tops become white, and soon afterwards are filled with a yellowish pus. These pustules seldom much surpass the size of a millet-seed. From the fifth to the seventh day each pustule bursts spontaneously; its sides shrink, and a slight oozing takes place, producing a brownish crust, which is very slightly adherent, and passes at its edges into the epidermic exfoliation from the inflamed surface immediately surrounding the pustule.

3. When the pustules are *clustered* or grouped in numbers the inflammation then extends to the subjacent cellular tissue, and occasions small, hard, and red inflammatory tumours, covered with pustules, or incrustations of considerable thickness, and of a mixed yellowish and greenish-brown hue. Most frequently, sycosis appears, like rosacea, in repeated partial eruptions, succeeding each other at irregular intervals. When the pustules break out repeatedly on the same places, the inflammation of the subjacent tissue occasions indurations and thickenings, which, with similar changes in the corion, present the appearances of large tubercles. These are most frequently observed in aged, cachectic, or leuco-phlegmatic persons, in whom resolution of the pustular inflammation is imperfect. When the eruptions have been extensive, or have succeeded each other rapidly, these tubercles increase in number, and spread over the skin or other hairy parts of the face. The pustules which continue to be evolved on the surfaces of these tubercles, or in the intervals between them, evince the nature of the affection. This advanced state of the eruption—this admixture of pustules, tubercles, and incrustations, imparts a disgusting appearance; and at this stage, sycosis is always obstinate, a cure being never obtained but with great difficulty.

4. Sycosis may be confined to the upper lip; the agglomeration of pustules on this part occasioning a thick brownish or blackish scab, greatly elevated above the surface. When the disease is prolonged or extensive, the skin often becomes much altered by it, and so swollen in parts as to appear covered by moist and vegetating tumours. The bulbs of the beard often participate in the inflammation, and the hair falls out; but subsequently, when the disease is cured, lighter and weaker hair is reproduced, and acquires greater strength. In very chronic and severe cases, the loss of portions of the beard is permanent.

5. When the disease yields to treatment, new pustules cease to appear; the incrustations are detached, and the tubercles or small tumours decline in hardness and size. Slight desquamations occasionally take place from the points formerly affected, which continue for a long time red or livid, especially in cachectic habits and aged persons, and in these particularly the affected parts retain their thickened and tuberculated appearance through the rest of their lives.

6. The *duration* of this eruption is never less than one, two, or three months: it often continues for years, notwithstanding the most rational treatment; and is apt to recur, after having been cured, in persons of faulty constitution, in those advanced in age, and after errors in diet and regimen. The continuance or recurrence of the causes of the eruption tends also either to prolong or to reproduce it.

7. ii. DIAGNOSIS.—The conical form of the pustular elevations, the bright red of the bases, the deep-seated connection of the pustules, and the purplish and indolent tubercles which succeed them, are characteristic of this eruption, which, however, may be mistaken for acne, ecthyma, impetigo, boils, and syphilitic eruptions. The situation and the relations of the pustules of sycosis to the hair distinguish them from *acne*. The pustules of *ecthyma* are larger and more highly inflamed than those of sycosis. The scabs following ecthyma are also broader, thicker, and more adherent, and are unconnected with tubercular elevations and indurations. The small pustules of *impetigo figurata* hardly rise above the level of the surface, and are not pointed like those of sycosis; they also differ from the latter in the greater rapidity of their evolution, and the more acute symptoms attending their progress. Although both these pustular eruptions may be disposed in groups, those of sycosis are most frequently isolated and distinct, whilst those of impetigo *figurata* are generally clustered. The pustules of the latter burst on the third or fourth day, and the fluid from them is quickly changed into continuous yellowish incrustations, which increase in thickness in the course of a few days. Those of sycosis, on the contrary, do not burst until the fifth, sixth, or seventh day, and the scabs which succeed are thin, slight, and isolated. All

these features are, however, obscured when the pustules of sycosis are copious and extensive, and give rise to a pale yellowish-green secretion, or when sycosis is severe and acute, and the pustules confluent or crowded; but even then, the thickening, swelling, and induration of the sub-cutaneous cellular tissue and corion, imparting a tubercular character to the affected part, will prevent any mistake. In *furuncle* the inflammation commences in the cellular tissue and extends to the skin, much pus and a sloughy core being expelled through an opening which leaves a scar. But in sycosis the inflammation first affects the hair follicles, and the pustules discharge only a small quantity of pus by a minute opening, which is speedily effaced without leaving a scar.

8. *Syphilitic pustules* very rarely are confined to the lower or hairy parts of the face. They most frequently appear on the alæ of the nose, forehead, and near the angles of the mouth. They are much flatter than those of sycosis, and instead of arising from bright red bases, as the latter do, they spring from coppery, dirty and almost flabby bases; and they are not preceded by the smarting or painful tension ushering the eruption of sycosis. The tubercles of sycosis may be more readily confounded with the tubercular syphilitic eruption; but those of the former are more conoidal, their bases are seated more deeply, whilst the syphilitic are more rounded, have a shining appearance, and are more superficial. They are, moreover, primary in their formation, whilst those of sycosis are consecutive of the pustules. The syphilitic eruptions are also preceded and attended by a variety of other morbid phenomena, which further serve to distinguish them, as sore throat, inflammation of the conjunctivæ, nocturnal pains, &c.

9. iii. The PROGNOSIS of sycosis is most uncertain; for it is impossible to state with certainty the period of its duration; and even when the decrease of the eruption and the appearance of the affected parts promise a speedy cure, fresh pustules often break out, without any apparent cause. In other cases, when the extent and severity of the eruption lead to the expectation that the disease will prove most obstinate, an active and judicious treatment may remove it in a comparatively short time. M. RAYER considers that those cases generally prove the most rebellious which, in the chronic state, preserve the pustular and primitive form.

10. iv. CAUSES.—The contagious nature of sycosis has been contended for by some writers, and denied by others. PLINY states that the disease, which he described by the name of *Mentagra*, spread in Italy by contagion. If this disease was actually not sycosis, it was very closely allied to it. M. FOVILLE states that he has seen several of the insane patients in the hospital of Rouen successively attacked with this affection from having been shaved with the same razor. Admitting the disease to be contagious, circumstances cannot often favour such an occurrence, especially in such a manner as will demonstratively manifest the fact. Sycosis most frequently appears in adult males (very rarely in females) of a sanguine or bilious temperament, who have thick and strong beards; and occasionally among the aged, more especially among those who have been habitually used to strong heats, as cooks, founders, refiners, and workers in glass and metals. The abuse of spirituous liquors, indulgence in the luxuries of the table and highly-seasoned food, and similar causes, have been supposed to occasion it; but these may more rationally be considered as causes which concur to perpetuate it, or to render it more remarkably chronic than to originally produce it. The want of due cleanliness, irritating applications to, or rancid matters allowed to remain in contact with the parts affected, the use of a foul, or blunt, or rough-edged razor, are much more likely to excite this eruption than those other causes to which it has been sometimes imputed. It appears more frequently in spring and autumn than at other seasons.

11. Dr. GRUBY, of Vienna, has lately contended that favus is occasioned by a vegetable formation, and that such a formation, of the cryptogamic kind, is found in the roots of the hair of the beard in this affection, and around that portion which is contained in the hair-follicle. The seeds of this vegetable formation, for which he proposes the name of *mentagrophite*, he believes to be the source of the contagious nature of the disease. On examining this affection with the microscope, the scales appear to be composed of epidermic cells, but the whole of the dermic portion of the hair is surrounded by cryptogamic formations, which constitute a vegetable sheath around it, in such manner, that the hair may be likened to the finger surrounded by a glove. These cryptogamia never rise above the surface of the epidermis: they originate in the matrix of the hair and in the cells of which the follicle is composed, and they ascend so as to surround all that portion of the hair included within the dermis. "They present everywhere a prodigious number of sporules, which are adherent on the one side with the internal surface of the follicle, and on the other with the cylinder of the hair: to the former they are very closely connected. Each plant is composed of a stem of several branches, and of sporules."

12. v. TREATMENT.—The causes, both exciting and concurring, should be removed; and the hair cut close with curved scissors, particularly if the use of the razor aggravate the affection. In some cases an emetic will be given with advantage, but it should be followed by stomachic purgatives. If the local inflammation be considerable, leeches may be applied; and if the patient be plethoric, a general blood-letting may precede them. Local emollient applications should be first employed, and these ought to be followed, especially as the disease becomes chronic, by applications which contain the chloride or bichloride, or the proto-nitrate, of mercury, in the form either of ointment or lotion. Ointments containing the iodide of sulphur, or the iodide of potash and sulphur, or even sulphur only, are most successful, especially when emollient applications, or vapour douches, or warm water douches, are used in the intervals between the employment of these ointments. In some cases a restorative or tonic constitutional treatment is required, and alterative mineral springs and waters are often of service. The hair, especially when it becomes loose, should be removed from the seat of eruption; and, if the affection become very chronic and obstinate, the application of the mineral acids, or of the caustic alkali, or the nitrate of silver, or even of the chloride of zinc, may severally be tried. Great care should be taken, in

this affection, as well as in others, for which ointments may be required, that they are recently made. In a case to which I was lately called, the zinc ointment was prescribed after the use of emollient applications, and was found quite rancid and most injurious *at five different chemists'* in the outskirts of the town where it was had; but when this ointment was procured from a respectable chemist in town, it was quite successful.

SYMPATHY AND SYMPATHETIC ASSOCIATIONS OF DISORDER.

— Synon. — Morbid Sympathies. — Συμπαθια or συμπαθεια, (from συν, with; and παθεω, I feel or suffer; or παθος, feeling, affection, suffering);— *Sympathia*, Lat.; — *Consensus nervorum*; — *Partium Consentio*, Auct.;—*die Mitempfindung*, *Sympathie*, Germ.; —*Sympathie*, Fr.;—*Simpatia* Ital.; —*Morbid Sympathies*.

Classif. — Physiological Pathology;— General Pathology;—Semeiology.

1. Definit.—Sympathy cannot be more correctly defined as it has been by Dr. Klein Grant, as follows:—"*That relation of the organs and parts of a living body to each other, whereby an action excited in one part, induces a corresponding action in another part.*"

2. Baglivi attributed the sympathies to membranous connection; Bordeu to the cellular tissue; Willis and Vieusens to the agency of the nerves; and Whytt and Broussais chiefly to the brain. Rega divided the sympathies into those of sensibility and those of contractility — a division which has much to recommend it. Bichât made some excellent observations on the relations subsisting between the sympathies and the different parts of the nervous system; but, although these observations were calculated to lead to a more correct arrangement of the sympathies than had formerly been offered, they have not yet produced this result. The writings of Unzer, far in advance of their age, had previously furnished much that was calculated to increase our knowledge of sympathetic phenomena; but this was physiological rather than pathological, and without sufficient practical application. Bichât appears to have been ignorant of the works of Unzer. Contemporaneously with the former, Prochaska examined physiologically sympathetic phenomena, when treating of the sensorium commune and the consensus nervorum, in his treatise on the Functions of the Nervous System, and, whilst he recognised what had been done by Willis, Whytt, Stahl, Unzer, and others, explained the phenomena by means of the sensorium commune, to which he referred the consensus nervorum.

3. In 1824, I defined sympathy to be, *that state of an organ or texture having a certain relation to the condition of another organ or texture, in health and disease; or, a related state of the vital manifestations or actions in different organs or textures, as, when one part is excited or affected, others are likewise affected or disordered*. I then classed sympathies into the *reflex* and the *direct*; the former taking place through the instrumentality of the sensorium, the latter being independent of it, and occurring through means of the ganglial nerves, and chiefly of those which form communicating chords between the viscera and of those which are distributed to the blood-vessels.

4. Subsequently Dr. M. Hall referred many of the phenomena usually ascribed to sympathy, especially those which I denominated reflex, to a reflex function of the spinal chord, which function he considered to occur independently of the brain, or even of the sensorium, that is, supposing the sensorium to be seated in the brain. But, that the sensorium commune is actually seated only in the brain, has been, and still is, doubted. Willis considered that there is a rational and a corporeal sensorium; and Unzer long subsequently adopted the same idea, or nearly the same idea; which was more fully developed and modified by Prochaska. This last writer subdivided this principle into two elements, namely, the sensorium commune of the soul, which is seated in the brain only, and reflects those impressions of which we are conscious, and the sensorium commune of the body, which is seated in the brain, spinal cord and ganglia and plexuses of the sympathetic system. But, wherever seated, there is evidently only one sensorium commune, which takes cognizance of impressions, and reflects them to distant parts, or, by means of which impressions, movements, &c., become sensations, or objects of consciousness or sentient operations, whether lively or faint, thereby constituting the class of reflex sympathies attended by consciousness. That this great principle may be seated in the basilar or central parts of the brain and medulla oblongata is very probable; but that it extends also to other or more distant parts and is independent of these centres of conscious or sentient actions, are not so admissible; for it is more reasonable to infer that those movements or actions which are unattended by consciousness, may be the results of a direct consensus of nervous action, or of a reflected consensus from ganglial or subordinate nervous centres, that either is not conveyed to, or does not reach the seat of conscious sensations, or which, owing to the state of this principle, or of its seat, fails to excite, rouse or effect it.

5. It is obvious that, if we attempt to arrange those sympathies which depend upon a consensus of the nerves, the classification must be made either independently of any reference to consciousness, or with so strict a regard to this principle as to assign to it a higher attribute than that which a simple nerve-action involves. If, however, we neglect such reference, any arrangement of nervous sympathies must be imperfect; and if we pay due regard to it, the difficulty of classification is greatly increased, seeing that the simplest and most direct consensus, such as those which concern the ganglial nerves, and which ordinarily occur independently of sensation, may become objects of the most intense sensation, the same change also taking place in respect of reflected sympathies, which may or may not be attended by consciousness, according to the intensity of the cause producing them, or to the state of the sensorium or of its seat. Hence it may be preferable to arrange sympathies with reference

to the superadded attribute of consciousness, but not to assign an order of sympathies alone manifesting this attribute or principle, seeing that there are few or no nervous sympathies, which may not, by intensity or otherwise, be attended by it, or excite it. Conformably with this view, therefore, I have offered the following arrangement, which I have more fully developed in the sequel — 1st, *direct sympathies*, transmitted directly either by nervous communications, or by continuity of structure, &c.; 2nd, *indirect or mediate sympathies*, conveyed by vascular communication, by states of the fluids, &c.; 3rd, *reflected sympathies*, curring through the media of the several orders of the nervous system, with or without consciousness.

6. From the time of WILLIS until those of UNZER and PROCHASKA, sympathy and consensus of the nerves were generally viewed as synonymous; and this consensus being supposed to depend upon the sensorium, it became a great difficulty to explain how this consensus took place with consciousness in some cases, and without consciousness in others. It was therefore inferred, that the consensus which involves this principle, takes place in the brain, and excites or impresses the mind or soul; and that the consensus which fails of impressing the mind, is seated throughout the frame in the several parts of the nervous system; the former being the mental consensus, and depending upon a mental or soul sensorium, the latter being a corporeal consensus, and depending upon a bodily sensorium. Thus these physiologists divided the sensorium into two essences or manifestations, the one with, and the other without consciousness, the latter, however, being only nerve-action, or the vital manifestations of the nervous system, which are unattended by consciousness, and which constitute an important, indeed the most extensive and important, part of those phenomena, which are comprised under the head of morbid sympathies.

7. The subject cannot be better illustrated, nor the observations I intend to offer on sympathy better introduced, than by adducing the remarks of PROCHASKA respecting it; and these cannot be more clearly conveyed, than in the words of Dr. LAYCOCK, who has most ably translated and edited the dissertation of this writer on the Nervous System, for the *Sydenham Society*. "That point of the nervous system is termed the common sensorium (*sensorium commune*), in which external impressions meet, and from which internal impressions are diffused to all parts of our body; in which, consequently, the consensus of the nerves takes place that is necessary to life, and in which external impressions are reflected into internal impressions, according to the law of self-conservation, with or without consciousness.

8. "That sensorium in which impressions are reflected with the consciousness of the soul, may, be termed the soul-sensorium; and the other, the corporeal sensorium; just as WILLIS has already divided it, into the rational and the corporeal soul.

9. "The brain, only, is the seat of the soul sensorium; the seat of the body-sensorium is the brain, spinal cord, and (as all observation shows) the ganglia and plexuses of the nerves. That external impressions can also be reflected in the brain, without consciousness, is shown by the involuntary convulsions of voluntary muscles. Monsters, born without brain and spinal chord, and which live up to the moment of birth, show that the consensus of the nerves necessary to this form of life, imperfect though it be, may take place, and that there may be a corporeal sensorium independently of the brain and spinal chord, and which, consequently, must be constituted by the plexuses and ganglia of the nerves. The movements observed to take place on irritating the nerves of a headless frog, and seen also in decapitated men, prove the same thing. The sympathetic nerve appears likewise to reflect its impressions in its ganglia and plexuses without the consciousness of the soul.

10. "In accordance with this consensus of the nerves, as well in the brain as in the spinal chord, ganglia, and plexuses, the operation of a stimulus is not limited to the nerves immediately irritated, but is extended to distant nerves, in known or unknown connection with the irritated nerves; and this is demonstrated by innumerable examples of consensus of nerves (consensus nervorum), as, for instance, the irritation in the pregnant uterus often causes nausea, vomiting, headache, toothache, &c.

11. "Both the soul-sensorium and body-sensorium operate according to the law of self-conservation, a truth which may be illustrated by numerous examples. For instance, the irritation or impression of too strong a light goes to the optic nerve, from whence it can only get at the ciliary nerves through the brain, and induce contraction of the pupil, so as to exclude the too vivid light from the eye, and obviate its unpleasant impression."

12. By most writers the term, consensus nervorum, has been viewed as synonymous with those nervous sympathies which occur in healthy persons, or which are not essentially morbid; whilst sympathy, according to its etymology, is considered by many as applicable only to associated morbid phenomena. The word *sympathy* has been viewed in both lights, and however correct the one may be, the other being the reverse, I shall respect common usage as regards it, and in order to prevent any misapprehension, use frequently the prefix, *morbid*, when discussing its numerous manifestations.

13. In attempting to illustrate *morbid sympathies, or those associated states of disorder which most frequently present themselves to the physician*, I shall first endeavour to classify them, conformably with the view above stated (§§ 5. 12.); and afterwards proceed to notice those which come more prominently before the medical practitioner, as fully as the plan and limits of my undertaking will permit. Many topics can be only briefly and imperfectly considered, whilst others may be barely enumerated, and offered to the reader, or to future inquirers, more fully to discuss or to illustrate.

14. ARRANGEMENT OF MORBID SYMPATHIES OR ASSOCIATED DISORDERS.

i. Definition of sympathies.
ii. Preliminary anatomical and physiological observations.
  A. The great extent and importance of the ganglial or the organic nervous system.
  B. The connections subsisting between the organic and cerebro-spinal nervous systems.

I. INQUIRY INTO THE MEDIA BY WHICH SYMPATHETIC AND SYMPTOMATIC PHENOMENA AND MORBID CONDITIONS ARE ASSOCIATED.

- i. *Direct or immediate sympathies.*
  - A. Direct communications by means of ganglial nerves.
  - B. Influence of ganglia on different organs or parts.
  - C. By direct communications by means of the cerebro-spinal nerves of sense and motion.
  - D. By continuity of surface or tissue.
  - E. By contiguity of organs and structure.
- ii. *Indirect or mediate sympathies.*
  - A. By vascular communications.
  - B. By states of the circulating fluids.
    - a. The chyle and other absorbed fluids.
    - b. The blood.
  - C. Owing to the conditions of the secretions and excretions.
    - a. By the various secretions.
    - b. By the excretions.
- iii. *Reflected sympathies.*
  - A. Reflected from nervous ganglia, often attended by spasm and altered sensibility of involuntary parts.
  - B. Reflected through the media of the ganglionated roots of the spinal nerves, and affecting the movements of voluntary parts.
  - C. Reflected through the medium of the spinal chord, and inducing morbid sensations or motions, or both.
  - D. Reflected through either the medulla oblongata or the brain, or both, and causing various disorders of sensation, of perception, and voluntary action, &c.

II. CIRCUMSTANCES INFLUENCING THE CHARACTER, NUMBER, AND INTENSITY OF SYMPATHETIC PHENOMENA.

- i. *Race and temperament,*
- ii. *Habit of body.*
- iii. *Sex.*
- iv. *Age.*
- v. *Physical power.*
- vi. *Occupations,* &c.

III. CLASSIFICATION OF MORBID SYMPATHIES, OR OF SYMPTOMATIC OR ASSOCIATED DISORDERS.

i. ASSOCIATED AFFECTIONS OF DIGESTION AND ASSIMILATION.

- A. *Disordered states of digestion and of assimilation associated with each other.*
  - a. Associated disorders of the stomach and liver.
  - b. Associated disorders of the liver with the intestines.
- B. *Morbid sympathies between the digestive organs, and the secreting and excreting functions.*
  - a. Between the functions of digestion and the urinary functions.
  - b. Between the digestive functions and the skin.
  - c. Between the functions of digestion and fæcation.
- C. *Sympathies between the digestive and the circulating and respiratory functions.*
- D. *The sympathetic and symptomatic relations between the digestive organs, the brain, and the organ of sense.*
- E. *Sympathies between the functions of digestion and locomotion.*
- F. *Associated disorders of the digestive and the sexual organs.*

ii. SYMPATHETIC AND SYMPTOMATIC PHENOMENA CONNECTED WITH THE CIRCULATING AND RESPIRATORY FUNCTIONS.

- A. *Mutual influences of these functions.*
  - a. From nervous connections.
  - b. From the nature of the functions themselves.
  - c. From their actions on, and the reactions of the blood.
  - d. From physical agents acting on the blood and on the respiratory and circulating organs.
  - e. From mechanical and other impediments to the circulating apparatus.
  - f. Influences of these functions, and their symptomatic relations in acute diseases.
  - g. Symptomatic relations of these functions in chronic diseases.
- B. *Morbid sympathies of the circulatory and respiratory functions with the digestive functions.*
- C. *Sympathy between the vascular and respiratory functions, and the brain and organs of sense.*
- D. Associated morbid states of circulation, secretion, and excretion.
- E. Association of disordered excreting function, with disorder of the vascular, nervous, and muscular systems.

iii. ASSOCIATED STATES OF DISORDERED SENSATION AND SENSIBILITY.

- A. *Sympathetic and symptomatic states of the several senses.*
  - a. With the functions of digestion and excretion.
  - b. With states of the brain and spinal chord.
- B. *Sympathetic relations of sensibility.*
  - a. With the organic functions.
  - b. With states of the cerebro-spinal centres.
  - c. With the reproductive organs.

iv. ASSOCIATED AFFECTIONS OF VOLUNTARY MOTION.

- A. *Sympathy between the functions of sense and locomotion.*
- B. *Associations of mental emotion and locomotion.*
  - a. Arising from the exciting emotions.
  - b. From depressing emotions.
- C. *Sympathies between organic and animal or voluntary motions.*
  - a. Organic or involuntary motions extending to voluntary muscles or organs, and rendering the actions of these involuntary.
  - b. Voluntary motions affecting the organic or involuntary actions.
  - c. Associations of the organic and voluntary motions in the functions of reproduction.

v. SYMPATHIES OF THE ORGANS OF REPRODUCTION.

- A. *Sympathies between these and the digestive and assimilative functions.*
- B. *Between the several organs and the cerebro-spinal functions.*
  - a. Between these organs and the brain.

b. Between these and the spinal chord and voluntary organs.

C. *Between these organs and the functions of sense and general sensibility.*

vi. CONCLUDING REMARKS.—As to the importance of observing closely sympathetic and symptomatic phenomena, and of tracing their origins and relations, with reference not merely to diagnosis, but also to prognosis and treatment.

15. A due recognition of morbid sympathies, or of those associated states of disorder which most frequently present themselves in practice, of the media of their connection, of the modes of their supervention, and of their extent, is of the greatest importance to the physician in enabling him to form a correct diagnosis and prognosis in most of the diseases which come before him, and to arrive at rational indications of cure.

16. i. DEFINITION. — *Morbid sympathies may be defined to be associated states of disordered function, or of diseased action ; the disorder or disease of one system, or organ, or part, affecting other systems, organs, or parts, according to their organic connections, their functional relations, and their several tendencies, or acquired or constitutional predispositions ; the consecutive sympathetic disturbance often being more prominently manifested than the original or efficient morbid condition, and thereby frequently concealing or masking this condition.*

17. ii. PRELIMINARY OBSERVATIONS. — It is necessary to a due consideration of this subject, that, before I proceed to notice the more remarkable morbid associations occasionally presenting themselves in practice, I should take *an anatomico-physiological view of the media or channels by which one organ or part sympathises with, or becomes affected by, the morbid conditions of another organ or part.*

18. The modes of explaining these morbid associations or sympathies, adopted by previous writers, are various and unsatisfactory, and have been generally based upon the prevalent doctrines of the day ; consequently the recognition of sympathetic, symptomatic, or associated morbid states, has been imperfect, the classification of them arbitrary or conventional, and the chains of connection existing between them imperfectly or erroneously traced.

19. Dismissing, therefore, all reference to the few writers who have considered the subject, I shall view it conformably with the inferences at which I have arrived, from researches which have engaged my attention on various occasions during the last thirty years.* But I can only imperfectly accomplish my intention within the limits to which I am confined, and must merely touch on certain points, which, to do them justice, would require a much more extensive elucidation.

20. *A.* There are certain circumstances in the *anatomy of the organic nervous system*, which, when kept in recollection, serve remarkably to explain many phenomena hitherto imperfectly accounted for. Much difficulty and misapprehension, in tracing the connexion of the sympathetic or associated morbid states, have arisen from the usual modes of viewing the large nervous masses, as giving origin to the nerves, or as being themselves a congeries of ganglia of a peculiar constitution. It would be much more conformable with a comprehensive view of the nervous system through the various grades of animal organisation, and with the development of this system in the more perfect animals, if the nerves, and especially the sensory and those of organic life, or ganglial nerves, were viewed as originating in the several tissues or structures themselves, more particularly in the organs of sense, in the cutaneous and mucous membranes, in the serous and fibrous tissues, &c. This idea, entertained and published by me many years ago, subsequent observations and reflections have tended to confirm.

21. Another important circumstance, one which I have also insisted upon for many years, which was formerly disbelieved, but is now fully confirmed by recent researches — namely, that all secreting organs are supplied with organic or ganglial nerves. The modes in which the viscera, both abdominal and thoracic, are supplied, are well known — namely, *first*, by fibres proceeding from numerous ganglia and plexuses, or, according to the view just stated, by fibrils originating in the organic or ganglial corpuscles, which, by microscopic aid, have been detected not only in the softer ganglia and nerves themselves, but also through the muscular tissue, the skin, the serous and the mucous surfaces ; or, in other words, from fibrils originating in organic or ganglial corpuscles, and proceeding centripetally to form plexuses or ganglia in the various abdominal, thoracic, and pelvic viscera. *Secondly*, by the organic or ganglial febrils interlacing and surrounding the coats of arteries. As far back as WINSLOW, the soft or ganglial nerves were traced in the large arteries, and he represented them as forming a net-work around these arteries. In 1816, 1817, and 1819, this subject engaged my attention ; and I was enabled by the microscopes then in use, which were of weak power, to trace the ganglial nerves, when the parts had been macerated for a short time in spirits of turpentine or spirits of wine, or diluted acetic acid, as far down as the lower third of the femoral artery ; and my more recent researches have shown that numerous fibres proceed from the sympathetic ganglia to the gangliated roots of the spinal nerves, and thence are ramified, on the one hand, to the chord itself, and on the other, along with the spinal nerves, to the extremities and general surface. When they reach the extremities, especially near the surface, and in the vicinity of the several joints, and even as low as the ankles and wrists, they become intimately associated with sensory nerves, forming with them, small or minute ganglia, and supplying with minute fibrils the synovial surfaces. The obvious intentions of this organisation may be inferred to be — 1st, that the sensory function and the ganglial functions should be associated ; and, 2nd, the vessels furnishing the secretion to the synovial surface shall be rein-

---

* I should not now have here entered so fully as I have done on the present inquiry ; but certain views comprised by it, engaged much of my attention, and not a little of my time many years ago. And when they were first published (in 1822 and 1824), they were considered by many as heterodox and visionary. They have, however, received support from the more recent researches of several eminent inquirers ; and they alone of existing doctrines are capable of accounting for the *sympathies or associations of morbid function and action*, although so succinctly and imperfectly considered in this article.

forced by organic nervous energy, for the promotion of synovial secretion. The communications of the ganglial nerves with the sensory nerves and spinal chord, the numerous branches proceeding from the splanchnic ganglia to the sympathetics, and thence to the ganglionated roots of the spinal cord, and to the cord itself, explain many of the phenomena remarked in the course of diseases of the abdominal viscera, on the one hand, and of diseases of the spine, spinal cord, and joints on the other. When diseases of the joint go on so far as to produce disorganisation of the parts, we commonly find that the digestive organs sympathise more or less with them, so that loss of appetite, and even vomiting, not unfrequently supervene.

22. I have elsewhere contended, that the nerves supplying the synovial and mucous surfaces and integuments should be viewed as originating in the nervous corpuscles distributed to these parts; or, in other words, that delicate fibrils arise in, and are connected with, these corpuscles, coalesce in the extremities with the sensitive fibres, form minute ganglia with these latter, and run thence, or rather converge, towards the spino-cerebral axis. Thus, whilst the *splanchnic and sensitive nerves* may be viewed as arising in, or commencing from, the nervous corpuscles already noticed as existing in the several surfaces, viscera, and organs, and as interlacing or communicating freely with each other, and with nerves of motion, as well as supplying the circulating systems, the *motory nerves* proceed in an opposite direction. The *former converge* towards the centre, communicating with the encephalon and nerves of sense; the *latter diverge* from the spinal centre to the periphery, also communicating with the brain, from which proceed the impulses of volition by which they are influenced. The *one* class is acted upon by mental impressions or volition; the *other*, by physical causes or agents.

23. The nerves may thus be divided into *three classes*, namely — 1st, the splanchnic or visceral, or those of digestion, assimilation, circulation, and secretion; 2nd, those of general and special sensation; and 3rd, those of volition, or muscular action or motion.

24. *B.* But it is important to bear in mind *the character of the communication between these orders of nerves*, inasmuch as such communications give rise to numerous states of healthy or morbid action, and occasion, mutually, various affections of the large or nervous centres. The connections between the organic nerves and the roots of the spinal nerves, and the nerves of sensation, have not been investigated till recently; and even now not so fully as is required. This much, however, may be remarked generally, that the organic or glanglial nerves are more or less connected with all the nerves of sensation; and where the connection is formed, or where these different nerves closely approach each other, we generally find minute ganglia.

25. It has been a subject of discussion, viewing the brain as the secreting organ, as it were, of the manifestations of the mind, how the brain itself is supplied with organic or ganglial nerves. We know that the vessels of the brain, the carotids and other arteries, are all surrounded by ganglial or soft nerves; still this is an insufficient supply of these nerves, if we consider the analogy existing between this organ and the other organs of the body, — if we view the brain to be like other viscera; inasmuch as we find in other viscera, that, beside the ganglial nerves, thus distributed to the blood-vessels, there are also special ganglia, which are intended for the further supply of nervous energy to them. Take, for instance, the liver; there are, besides the organic or soft nerves supplying the blood-vessels, several ganglia and plexuses supplying the structure of the viscus itself. Take the kidneys; there are also specific ganglia devoted to the maintenance of a certain and constant amount of nervous energy, probably modified in kind, or suited to the functions of these organs. It is not, however, so manifest that the brain enjoys a similar supply of ganglia and ganglial nerves, or that the supply of these nerves, furnished through the medium of the blood-vessels, is at all sufficient for the several functions or manifestations of the brain, viewing these functions as depending upon the organic nervous ganglia and ganglial ramifications, as observed in respect of secreting viscera and organs. Hitherto the sufficiency of the supply of ganglial nerves sent to the brain with the blood-vessels has not been demonstrated, and hardly admitted; and special sources of such supply as exist in connection with the other viscera, have not been satisfactorily shown, granting that the organic nerves supplying the blood-vessels of the brain are insufficient for the discharge of the functions of this organ.

26. It has been considered, and most probably with truth — indeed I have on several occasions contended — that the pituitary and the pineal bodies are, in fact, organic nervous ganglia, inasmuch as there are communicating branches or fibrils running between the other ganglia, at the neck and about the base of the skull and these bodies. But, in opposition to this view, it has been argued that these bodies are different from other ganglia in the body. However, as all the ganglia may be considered to have a minute special organisation, according to the functions to be performed by the organ which they supply, and as the functions of the brain are so very different from those of other parts of the body, so may the ganglia, distributing their prolongations and fibres to this organ, be reasonably considered to differ also from others. These bodies are connected likewise with the soft commissures and grey substance of the brain. In fact, these bodies, like the ganglia, as well as the grey substances of the brain and spinal chord, which are the active portions of these organs, abound with organic nervous corpuscles; and they are connected, by means of delicate grey fibrils with the plexuses surrounding the arteries, and with the ganglia in the head, especially with the ganglia of RIBES, CLOQUET, and MECKEL. The difficulty has been to trace this connection; and unless it be admitted that these bodies are, in fact, ganglia, devoted to the office of supplying vital energy to the brain, to enable this organ to discharge its functions, we are at a loss to account for their functions. These bodies are lodged more securely than other parts from danger; they are placed near the base of the brain, and in situations the least likely to suffer from injury; and they are in connection with the commissures of the brain, where it is believed the functions of volition connect themselves with those of perception and intellect.

27. Although it is difficult to trace the connections of the ganglial nerves with the brain and the nerves of special sense, it is not so difficult to ascertain the connection of the ganglial nerves with the spinal chord and spinal nerves. The spinal nerves, especially those of volition, are all white and tubular, and are not provided with the organic nervous corpuscles seen in the ganglia and their nerves; whilst the latter are soft, grey, and ramify in an irregular and indeterminate manner, compared with the former. Now the ganglial or grey nerves, as already stated, may be traced from the sympathetics into the gangliated roots of the spinal nerves, and fibrils proceed thence to the chord itself, whilst others may be traced in an opposite direction, or from these roots, along with the spinal nerves to the extremities and surface of the body. On the other hand, ramifications of the white or spinal nerves run to the ganglia of the sympathetic nerves, and in some situations, especially in the pelvis, may be traced into the splanchnic ganglia. Thus there are — 1st, communicating branches of grey nerves running from the ganglial system to the spinal roots and chord; and, 2nd, communicating branches of white or spinal nerves proceeding from the chord to the sympathetic and ganglia. Hence the functions of each department of the nervous system are mutually aided; and impressions made upon one part of either system are extended in a more or less sensible manner to other parts.

28. The ganglia placed on or near the pelvic viscera, admit of the clear recognition not only of the intimate structure of the splanchnic ganglia, but also of the presence of white nerves, which either terminate in them, or proceed through them, and which come in greater numbers, or more palpably, from the spinal chord to them, than to any other ganglia. Thus the generative and urinary organs are supplied not only with gangial or splanchnic nerves, but also with spinal nerves, a supply of nerves from both nervous systems being necessary to the due discharge of their functions,—and the supply of each of these different orders of nerves to each of these organs is in due relation to the functions which each discharges. Thus, also, the generative organs are supplied not only with the organic nervous influence, but also with the nervous influence generated by the brain and spinal chord. And, moreover, the special ganglia devoted to these organs are mutually connected by means of communicating branches, both with the other splanchnic ganglia and with the cerebro-spinal axis.

29. I have been thus particular in directing attention to the communications between the different systems of nerves, because we are thereby enabled to explain many phenomena which occur in the course of disease. It may be, therefore, inferred, in brief, that these different orders of nerves communicate mutually by means of branches going from one to the other; and generally ganglia or plexuses are formed at or near the points of communication. There thus arises an interchange of influence, tending to the proper discharge of function; and mutual sympathy is developed when an impression is made on any one part of the circle formed by this communication and organic connection, the effects varying with the nature of the impression.

30. *C.* It is impossible to arrive at just conclusions as to the sympathy or mutual dependence of parts, without reference to *the vital property of irritability*, and the relations of this property with the nervous system. Almost up to the present day, especially from the days of Haller, irritability was considered as a function of the muscular fibre, — as a *vis insita* in that fibre, and not dependent upon the nervous system. Many years ago (in 1819, 1820, and 1821), I directed particular attention to the subject of irritability of different structures, and tried many experiments, especially in some of the lower animals; and, from these experiments and observations, I then came to the conclusion, that the irritability of fibrous and muscular parts depends upon the organic nervous system; and much more recently, this doctrine was advocated by Dr. Fletcher, in his works on Physiology, he making a due acknowledgment to me as having originated it.

31. In the first place, all irritable fibres present, when under the microscope, a more or less abundant supply of those corpuscles in which organic nerves may be said to originate, and, in fact, from which the organic nervous fibres have been detected by the microscope to take their origin, — from which they arise or proceed, and with which they abound. The involuntary muscles, and the fibrous membranes of the hollow or tubular viscera, are supplied only with soft nerves, — have no other nerves than ganglial; and they possess great power of contraction both in health and disease. This power may be traced, to a certain extent, even in the membranous portion of the trachea and bronchi; and if we refer to the comparative anatomy of these parts, especially to the trachea of some of the higher animals, we find a singular conformation of the cartilaginous rings, remarkably well calculated to antagonise the contractile force of the fibrous structure of the membranous portion of the tube. These rings are, indeed, the antagonists of the contractile power of the fibrous structure, preserving at the same time a patent state of these tubes, and admitting of a certain degree of contraction when this structure, or the soft nerves supplying it, are irritated. This conformation is very remarkable in ruminating animals, and well calculated to prevent the tracheal canal from being diminished or injuriously pressed upon during deglutition and rumination.

32. Although involuntary fibrous structures are supplied only with organic or soft nerves, and notwithstanding that the structures receive no white or voluntary nerves, nevertheless they are impressed or acted upon by the electro-galvanic influence. In 1820 and 1821, I instituted some experiments to determine the contractility of fibrous membranes, but the galvanic agency did not appear to produce much effect unless the power was very considerable. When, however, this agent is applied to the nerves of motion proceeding to voluntary muscles, the effect is very remarkable. It would appear that the voluntary muscles are supplied with voluntary or spinal nerves in addition to the supply of soft nerves received or possessed by all fibrous structures, bestowing thereby upon these muscles a voluntary and a greater power of contraction; the power and character of contraction thus varying with the nature and conformation of the muscular parts, and

with the nervous centres which supply these parts with nerves. I can scarcely follow this subject further inasmuch as I have to notice other topics that will occupy much of my limits; but it is more fully discussed in my notes to RICHERAND's *Elements of Physiology*, and in the articles "IRRITATION" and "IRRITABILITY." I have there contended that irritability depends on the organic or ganglial nervous system; and that it is exalted in the voluntary muscles, by the terminations of the motor or voluntary nerves.

33. The irritability of the heart is very remarkable. I have had opportunities of investigating it in the hearts of a number of animals, and in several fishes, — the halibut, the skate, the turbot, the cod, ling, &c. From all these, the heart may be cut out, and it will still contract for a short time after it has been separated from all nervous and vascular connections; thus showing, that not only does it take a considerable time for the influence of the ganglial nerves supplying an involuntary organ to be exhausted, but that the numerous plexuses and small ganglia, formed by these soft nerves under the serous linings and in the structure of the heart itself, and in the vicinity of blood vessels, still continue to supply nervous power to the muscular structure, and are of themselves sufficient for the continuance of the phenomena of irritability for a short time. Moreover, the heart appears to be plentifully supplied in its structure with those ganglionic corpuscles, which, as I have already stated, are intimately and organically connected with the soft, grey, or ganglial nerves; and which most probably also administer to its irritability. Owing to these provisions, a short period is required to exhaust the irritability of the organ, even when thus isolated or removed from all its connections. It is not surprising, therefore, when viewing the morbid relations of irritability, to find this vital property most remarkably modified — to observe it exalted, in one case, and depressed in another, or even otherwise altered in its condition, by agents which impress the organic nervous system, by changes in the vascular system, especially by alterations of the blood, and by the state of the cerebro-spinal nervous influence.

34. *D.* But it is not in connection with *irritability* only that the functions of the ganglial and sympathetic nervous system should be viewed. This part of the nervous system, or, more correctly, this distinct and separate system — this organic or primary nervous system — presides also over secretion and excretion, as I have already stated. If we view the digestive canal, which possesses both the vital property of irritability, and the no-less vital property of secretion — the former in connection with its muscular tunics, the latter with its villous coat and glandular apparatus — we shall find that every part of this canal, more especially the stomach, duodenum, &c., is supplied with soft or splanchnic nerves; and that this supply is not limited to those fibrils which surround the arteries of these viscera, or to others which proceed from the semilunar ganglion, and aortic plexus; but that these viscera, as well as other secreting viscera, possess, in addition, numerous minute ganglia and plexuses under their serous and proper coverings, and near to the situations of the principal blood-vessels, which minute ganglia and plexuses are more especially devoted to the functions discharged by the organ or part in which they are situated.

35. Whether the splanchnic or ganglial nerves originate in these corpuscles distributed through an organ or membrane, and successively form themselves, first into fibrils, next into plexuses and minute ganglia, and afterwards into larger branches and more manifest plexuses and ganglia, until they converge into the semi-lunar and other ganglia; or whether they originate, as believed heretofore, in the ganglia themselves, and depart thence to their destinations in the tissues, may not be readily decided; but it is indisputable that they constitute a distinct system; that they send their fibres with the blood-vessels, and with the spinal nerves, to all parts of the body, especially to secreting organs and parts; that they supply both the brain and the spinal chord; and that they form more numerous plexuses and minute ganglia in the several viscera, than have hitherto been described or even supposed; whilst, on the other hand, the intimate connection existing between these nerves and the cerebro-spinal nerves is reciprocated by numerous ramifications proceeding from the spinal nerves, — from the intercostal, lumbar, &c., — which run to the ganglia and plexuses of the organic nerves, and either proceed through these, or terminate in them, or accompany fibrils from them to various parts, retaining more or less evidently their white and tubular appearance. In viscera possessing more or less of voluntary power in addition to the organic, as the urinary and sexual organs, the vicinities of the sphincters, and the outlets of canals, &c., the supply of the white and tubular nerves — motor and sensory spinal nerves — to the ganglia and plexuses more especially devoted to the functions of these organs and parts, is more abundant and more manifest than in others, these organs combining and requiring the influence of both these nervous systems in the discharge of their functions.

36. II. MEDIA OF MORBID SYMPATHIES. — Having thus directed attention to those preliminary topics which should be duly recognised before we proceed to inquire into the several media by which one organ or part sympathises with another, or by which the morbid condition of one organ affects another, I now proceed to a general view of the MEDIA AND MODES OF MORBID SYMPATHY, for there are not only different *media*, but to a certain extent different *modes*, by which these sympathies take place. Associated morbid states, or sympathies, have been above *classed* into — 1st, the *direct*; 2nd, the *indirect*; and 3rd, the *reflected*.

37. i. The FIRST CLASS has for its media, — *firstly*, the *direct communication of nervous fibres*, more particularly the organic nervous fibres; and here the influence of the nervous ganglia in the viscera becomes a matter of very interesting consideration: every important organ is supplied with these ganglia and plexuses, which are, there is every reason to believe, peculiar or modified in size, form, and minute organisation, according to the functions each organ has to perform; — *secondly*, continuity of surface or tissue: thus the state of the mucous membrane of the stomach affects the mucous surface of the mouth, the fauces, the pharynx, &c.; — and, *thirdly the contiguity of one organ or tissue to another*: during a state of disten-

sion the colon presses on the diaphragm, so as to affect the action of the heart and other parts; and flatulence of the stomach disorders the functions of the heart and diaphragm, &c. These constitute the chief direct media of sympathy between different organs — namely, nervous communication, continuity of surface, and contiguity of situation.

38. ii. The SECOND CLASS, or *indirect modes and media* of morbid sympathy, are — *first*, by *vascular communication*. It must be obvious that when a portion of a vessel is affected, another portion of it will experience more or less of disorder. We know, in cases of inflammation or irritation of a lymphatic vessel, how readily the morbid condition extends along it and affects the glands. Here vascular communication, even in these vessels, is a ready medium for conveying morbid action; and it is still more remarkably evinced in respect of the arteries and veins.

39. *Secondly*, by the states of the circulating fluids. This is one of the most important modes in which morbid action is propagated, and it is one which forms, as it were, the basis — the groundwork, of the system of *humoral pathology*, which for many years was believed in so generally throughout the civilized world. When the morbid affections of the nervous system were so much insisted upon by HOFFMANN and CULLEN, the humoral pathology became obscured, but closer observation and less addiction to theory, have shown, that the circulating fluids are readily and early disordered in the course of disease, and, being thus disordered, they become sources of a more general malady — of disease not limited to particular organs, but extending more or less to the whole œconomy.

40. iii. The THIRD CLASS, under which I have arranged morbid sympathies, is the *reflected*. That this is not a very recently recognised class of sympathies, is shown by the fact that it was so denominated and discussed by UNZER and PROCHASKA, and more fully by me, as early as 1824. The reflected sympathies are propagated or developed — *first*, by fibrils proceeding to, and communicating with, ganglia or plexuses, and supplying by means of these sources contractile and secreting viscera. Thus irritation occasions the contraction of a portion of intestine; the irritation being propagated most probably to a nervous ganglion, and then reflected in the form of contraction. But it is not improbable, and my recollection of the phenomena I have observed upon irritating visceral parts of the lower animals seems to warrant the inference, that irritation is followed by contraction in a more direct manner, or, at least, in the manner less obviously indirect, than that now mentioned; and contraction may follow irritation without the irritating impression being conveyed to ganglia remote from the organ or part irritated. Thus, when the hearts of some fishes are removed from all their connections, they will contract upon irritation for a short time, the minute ganglial and plexuses in the structure of the organ thus enabling them to react; and so on as regards other hollow organs admitting of a sensible reaction upon irritation.

41. *Secondly*, the reflected sympathies are developed by means of the communications of the organic or ganglial, or soft nerves, with the roots of the spinal nerves. I was first led to describe the mode in which sympathetic irritation is thus propagated to the muscles of voluntary motion by a singular case which came under my care in 1821, at the Surrey Dispensary. A female, of middle age, presented herself with violent contraction and relaxations of the abdominal muscles, alternating rapidly, regularly, and constantly. The spine evinced no tenderness when examined, no pain nor any other morbid phenomena; and the functions of the extremities and of the urinary organs were unaffected. Conceiving that the affection might be sympathetic of worms in the intestines, I prescribed full doses of turpentine and castor oil, which brought away enormous quantities of lumbricus teres and fæces; and as soon as these were evacuated the morbid action ceased. The irritation of the extremities of the nerves of the digestive canal evidently was in this case conveyed to the roots of the spinal nerves, and was thence reflected by the nerves of motion upon the abdominal muscles. It does not appear necessary to infer that, in this case, the irritation was conveyed to the spinal chord itself, inasmuch as neither morbid sensibility, nor other disorder could be traced to it. We can explain the phenomena by considering that morbid irritation was transmitted merely to the roots of the spinal nerves by the ganglial and sympathetic nerves, and that the irritation thus transmitted to these roots produced this affection of the abdominal muscles. The second class, then, of reflected sympathies are those reflected by the ganglionated roots of the spinal nerves.

42. *Thirdly*, irritations, or impressions, are reflected from internal viscera and internal parts, by means, or through the media, of the spinal chord and nerves to the voluntary muscles and extremities of spinal nerves, motion, or sensibility, or both being thereby affected, as shown in several diseases, more especially in hysteria, chorea, neuralgia, tetanus, &c.

43. The *fourth, or last order of reflected sympathies*, are those which take place through the medium of the *medulla oblongata or brain*, or of both. It has long been proved that impressions made on the organs of sense will occasion reflex actions. Indeed, all the phenomena of mind may be said, so far as they produce any sensible motion or action in the œconomy, to be reflected. This class of sympathies are attended generally in the waking state by consciousness, although not necessarily and uniformly; but during sleep, sensibility, or consciousness is only occasionally and obscurely excited.

44. III. CIRCUMSTANCES INFLUENCING SYMPATHETIC PHENOMENA. — Having sketched the several modes in which morbid actions or states become associated, and, at the same time, considering that these associations are often brought about through more than one channel, I proceed next briefly to advert to the well-ascertained fact, that irritations, or morbid conditions of any other kind, may exist in organs or parts without producing those sympathetic or symptomatic phenomena which we observe in other persons in a more or less marked degree; and that *sympathetic phenomena vary not only in degree, but also in some measure in character and variety, or number, with the temperament, with the habit of body, with the sex, with the age, with the physical powers, and with the occupations of the individual.*

45. i. It is difficult to determine in what degree

or mode the various sympathetic phenomena, manifested by the human subject may vary in the *different races of the species.* Judging from my own observation, I am inclined to infer, that they are most diversified, numerous, and manifest amongst the most highly cultivated and luxurious of the Caucasian race, and that they are the least diversified, and the least manifest in the negro and the hyperborean races.

46. ii. *Temperament, idiosyncrasy, or diathesis,* has evidently a great influence upon the sympathies — the nervous and irritable temperaments evincing the most varied and most numerous and prominent sympathies; the phlegmatic limiting their range and diminishing their intensity. In nervous, impressible, and excitable persons, irritation or excitement, on the one hand, or depression or exhaustion on the other, in whatever part of the œconomy it may exist, but more especially in sensitive and vital parts, is soon followed by various sympathetic changes, which either would not appear, or not appear to the same extent, in phlegmatic, robust, and muscular persons.

47. iii. Much, however, depends upon the *habit of body* and the vascular conditions of the individual. It may be difficult to determine correctly whether or no fat or very lean persons evince the more prominent range of morbid sympathies. Most probably, thin or lean persons are not only more susceptible of sympathetic phenomena, but also evince them more prominently than those who are the subjects of greater or less obesity. A similar difficulty exists respecting the greater influence exerted by vascular plethora, or by deficiency of blood. Probably both extremes, or even an approach to either extreme, may favour the development of morbid sympathies much more than a healthy state of the vascular system — than when a due relation subsists between the contained fluid and the containing vessels—between the healthy quality of the circulating fluids and the tone and energy of the moving powers.

48. iv. *Sex* has a most manifest influence upon the number, character, and prominence of the sympathies. In females, especially those of a nervous and impressible temperament, both the range and the intensity of these phenomena are most striking, and the phenomena developed are most frequently connected with irritation of a particular organ or part, and are attended by more or less morbid sensibility; the nervous systems being generally the media by which their sympathetic affections are developed. In proportion as nervous power is impaired, exhausted, or originally defective in this sex, the more remarkably are susceptibility and excitability manifested, and their more remote consequences evolved. The same remark applies also to males, but the sympathetic phenomena are not so manifest in them, unless in cases of great exhaustion of nervous power.

49. v. *Age* has also a very manifest influence upon the sympathies; the earlier the age, the more readily and rapidly are they developed by the primary morbid affection, and the less frequently are they connected with organic lesions. As life advances, sympathetic phenomena are less frequently and less rapidly evolved; and structural changes either proceed further without producing them, or produce them less frequently, with less severity, and in less variety. This is especially the case after fifty years of age, and after the latter climacteric age of females. At the period of female puberty, and about the period of the latter sexual change in this sex, sympathetic affections are frequent, prominent, and varied; and in many they continue, at intervals, to partake more or less of this character throughout the whole epoch of uterine activity. After the periods of dentition are passed, when the sympathies are most remarkable, owing to the relations subsisting between the state of the gums and both the ganglial and the cerebro-spinal nervous systems, the most important epoch of both healthy and morbid sympathy — or rather of synergy or physiological sympathy — is the epoch of puberty; after which sympathetic affections diminish in frequency and intensity in this sex, unless in crowded towns, in persons following sedentary occupations, and in the debilitated.

50. vi. The state of *physical power* has manifestly no mean influence upon the sympathies. Where this power has been originally great — where it is associated with nervous energy, and with perfect states of the digestive and assimilative functions — there sympathetic affections are least frequently and least severely complained of, and the least complicated. When organic nervous power is depressed or exhausted, more especially when the exhaustion has proceeded slowly, and continued long, a very different result is observed; the irritation of a particular organ, or part, then developes various affections, sometimes of the same, at other times of a different character, in different or several parts of the frame. Numerous instances illustrative of this pathological position present themselves in practice amongst both sexes, especially about puberty, and for many years afterwards, more particularly in the female sex.

51. vii. The *occupations* of life exert great influence upon the liability to severe or complicated sympathies. It is obvious that sedentary persons, or those occupied in ways which preclude the due exercise of the body in the open air, more especially if they pass much of their time in large towns, or in the impure air of factories, or in unhealthy localities, and those who exert the mind upon abstruse or abstract subjects, will sooner or later acquire an increased susceptibility of morbid impressions and irritations, and these irritations will in them develope a wider range, and a more intense grade, of sympathetic affections than in others not similarly circumstanced, all other things being equal. It is incompatible with my limits to pursue this subject further, or to illustrate my positions by referring to acknowledged facts. This, as well as what I shall have hereafter to advance, must be viewed rather as suggestive, than as sufficiently illustrative of the subject.

52. IV. SPECIAL CONSIDERATION OF SYMPATHETIC OR ASSOCIATED DISORDERS. — I next proceed to consider, in a more special manner, some of the sympathies most frequently observed in practice, and briefly to notice, or merely to enumerate, others. In the view I am about to take of *sympathetic* or *associated morbid states,* I shall consider in succession, *first,* the associated morbid states of digestion and assimilation; *secondly,* the sympathetic phenomena connected with the circulatory and respiratory functions; *thirdly,* sympathies, or associated morbid states of sensa-

tion and sensibility; *fourthly*, associated functions, or sympathies of animal motion; and *lastly*, the sympathies, or morbid states of the organs of reproduction. I should not have directed attention to this subject, if I had considered that former writers had discussed it fully; but I believe that it will be found, upon referring to pathological writings, that not much has hitherto been said satisfactorily upon it. That morbid sympathies are propagated throught he channels, I have attempted to point out, receives so frequent a confirmation, and is indeed so constantly observed in practice, that we may conclude that a person labouring under any specific disease, as described by nosological writers, is seldom seen without presenting important morbid associations and sympathetic phenomena. We rarely meet, in the course of medical practice, with a disease implicating one particular tissue or organ, without involving, more or less during its progress, distant, although related (related in the manner I have attempted to point out), functions or organs —without displaying various sympathetic phenomena, or associated morbid sensations, conditions, or actions, owing to the several relations which I have here attempted to establish. I now proceed to consider the *first Class*.

53. i. Associated Sympathies or Affections of the Digestive or Assimilative Organs.— These organs are most important as respects vitality; they are observed throughout the animal kingdom, and, as being intimately connected with the origin and perpetuation of life, demand our more immediate consideration. The sympathies, or associated states of digestion and assimilation, are to be referred,—*first*, to the circumstance of these organs being supplied with the same system or order of nerves, the ganglial, and, even according to the view I have suggested, of these nerves partly originating in the villous surfaces and parenchyma of these organs, as shown by the microscope; and to the presence of the organic nervous corpuscles, and their incipient arrangement into fibres, in these tissues and organs. The circumstance of the organic or soft nervous fibres originating thus, and the extension of these fibres to plexuses and ganglia, and thence to the nervous system of animal life, serve to show, or at least go far to explain the fact, that disorders affecting these organs, especially the alimentary canal, affect more or less distant parts, remote organs or parts thereby sympathising with them. *Secondly*, to the similarity and continuity of structure existing through a large portion of these organs, particularly the digestive canal. *Thirdly*, to the contiguity of their position. *Fourthly*, to the association of function and normal action. *Fifthly*, to the several vascular connections existing between them. Thus it is not through one channel only that these associations are kept up, for no less than five may be considered as contributing to the several states of morbid sympathies or associations which the digestive and assimilative organs present in practice.

54. *First*, the associations of the morbid states of the organs of digestion and assimilation with each other are amongst the most frequent and prominent in the human economy.—*A*. When we view the intimate connections existing between the digestive canal and its allied viscera, especially the liver and pancreas, by means of the splanchnic ganglia, plexuses, and ramifications, and of the vascular system, the frequency of these morbid associations cannot remain a matter of surprise. When we consider also the relations of the portal circulation, and view it (as it really is) as independent, in a great measure, of the action of the heart, indeed, so much so as that the return of blood from the liver is much more under the control of the heart, than the supply of blood to the organ by the portal vein,—or, in other words, that the return of blood from the hepatic vein is owing more to the action of the heart, than the circulation through the portal system is owing to this organ,—we must necessarily infer the operation of some other agency than the heart in carrying on this circulation. Now, the capsule of Glisson, and the ganglial nerves, with which both it and the portal vein are provided, are in my opinion the chief agents of this important and independent circulation,—agents which operate through the medium of their distributions throughout the organ along with this vein, and which influence not only the circulation of it, but also the circulation of the bile along the ducts. That this capsule at least contributes to, if it does not entirely discharge, this function, may be inferred from its organisation; for it is abundantly supplied with ganglial corpuscles and fibrils, and it may therefore be considered as exercising important vital functions. When, therefore, we reflect upon the nervous and vascular connections of the digestive organs, we must admit that affections of one of the series will be readily propagated to others, and that disorder of the functions of one will necessarily affect more or less the rest. We frequently observe in practice, that disorders of the stomach or bowels impede or otherwise affect the functions of the liver; and that torpor, obstructions, congestions, or other disorders of this organ, are followed by affections of the stomach, by congestions of the digestive mucous surface, and indeed of all the vessels which combine to form the portal system; and we have, as more remote consequences, when the original mischief remains, increased exhalations, hæmorrhages, hæmorrhoidal affections, jaundice, and even serous effusion into the peritoneal cavity.

55. Morbid states of the intestinal canal also remarkably affect the functions of the liver, through the medium of the splanchnic nerves, and by influencing the states of the portal system. Irritation of the mucous surface of the intestines, especially of the duodenum and jejunum, is readily propagated to the portal system, and this effect is the most rapidly developed in warm climates, where active determination of blood to the liver, and congestive and other forms of inflammation of it, are thus observed frequently to supervene. The intimate connection subsisting between these viscera pathologically is evinced also in fevers; and in these, both in the mode just adverted to, and in another of a different kind. In the course of fevers, hæmorrhages from the digestive mucous surface are not infrequent occurrences, and are most unfavourable as respects the vascular system generally, the portal circulation especially, and the vital powers. In yellow or hæmagastric fever, a fatal termination is generally by a black vomit, which consists chiefly of the blood that has exuded from

the mucous surface of the stomach, and often to such an extent as to leave the liver of a pale yellow colour, or altogether bloodless, upon dissection. In these cases, the blood, instead of being carried into the portal vein, is exuded from the digestive mucous surface, leaving the liver in a state of anæmia, especially as regards this vein. (See §§ 128, 129.)

56. *B. Contiguity or proximity of position* has a great effect in complicating diseases of the digestive organs. This is evidenced by inflammations and inflammatory fevers, more especially when the serous surface of either of these organs is affected. Owing to contiguity, the inflammation is rapidly propagated from one surface to another, not so much by continuity of surface as by contiguity of position. When making post-mortem examinations, I have often found that the opposite surfaces of different organs had become inflamed; that lymph had been thrown out from both at the place of contact, and yet the intervening portion of surface, where contact did not exist, presented no change — that is to say, the inflammation was not propagated by continuity, but by the contact of opposite surfaces: the lymph thrown out from the primarily-inflamed surface had acted as an irritant to the vessels of the opposite part, with which it came in contact, and given rise to inflammation; false membranes, or exudations of lymph, adhesions, &c., being the consequences.

57. Owing to continuity of surface, and similarity of structure, disease extends, — more especially erythematic, or asthenic, or cachectic inflammations, — along the mucous and serous surfaces, varying in severity in different viscera or situations. Thus inflammations extend not only downwards, but also upwards, — from the stomach to the intestines, — from the cæcum to the colon and rectum, — from the stomach to the œsophagus, pharynx, and fauces, — and from these latter to the trachea, bronchi, &c. Irritations or inflammations of the mucous surface of the duodenum may extend to the mucous surface covering the ducts, especially in weak or cachectic constitutions, in which this extension is most likely to occur; the extension of inflammatory action being most likely to take place in debilitated and cachectic persons, producing inflammation of the ducts, and even of the viscera, from which these ducts proceed; and the limitation of this action being equally favoured by vital or constitutional power.

58. *C.* The state of the muscular tunics of the digestive canal frequently gives rise to important sympathetic phenomena. When the colon is much distended with flatus, or irritated by sordes or morbid secretions, or accumulated fæcal matters, various changes occur, not only in the portion of the canal above the seat of these affections, but also in other parts in the vicinity. I have pointed out already, that, in such cases, owing to the nervous communication subsisting between the intestinal canal, the splanchnic ganglia, and the spinal nerves, numerous sympathetic disorders frequently also arise, especially pain in the joints, and various spasmodic affections. I refer merely to the very common phenomena of spasms of the limbs and lower extremities, occurring in bilious colic or in common cholera, and in poisoning by corrrosive or irritating substances.

59. *D.* When the circulation is interrupted through the liver, the digestive canal becomes materially affected; and, when the latter is deranged, then the former is disordered, and the portal circulation is also more or less deranged. Not only are the functions of the liver and digestive canal thus mutually disturbed in a very remarkable manner, but these disturbances also affect the urinary excretion and the kidneys. When the chyle is not sufficiently assimilated, or when the ingesta are of a character likely to produce inordinate excitement, or other derangement of the vasculari system, there are not only associated affections of the liver, through the portal system, but also, in consequence of the morbid changes taking place in the blood, further changes, more or less extensive, occur in the urinary excretion and organs, particularly in the kidneys. When individuals are otherwise in health, and the kidneys are enabled by nervous power to execute their functions, morbid matters, carried into the blood, are readily eliminated from it by these organs, producing various changes in the urinary excretion; but when the vital powers are weak, either from lesion of the spinal chord or nerves, or of the ganglia supplying those organs, or from general nervous depression or exhaustion, then there will be observed more or less serious disorder of the urine, or even of the kidneys themselves.

60. Even in comparative health we find a very intimate connection existing between the states of other excreting organs and the kidneys. For instance, when the functions of the kidneys are but temporarily obstructed, the blood to a certain degree becomes impure, and very important and deleterious elements, which should have been eliminated from the blood by these channels, are then either vicariously removed by other emunctories, the circulation being the while often more or less disordered, or the blood becomes contaminated and the vessels congested. Again, when the function of the cutaneous surface is materially deranged, — when it is suppressed, — if the individual is otherwise healthy, — if there is no disorder connected with the urinary organs, — these organs perform an increased function, and matters which should have been carried out of the system by the skin are removed by the kidneys, and often no severe disorder arises; but not unfrequently serious derangements take place, owing to suppression of the cutaneous function. Thus disease of the skin, or suppressed perspiration, or disorder of the urinary functions, often produces a number of morbid actions, — at first vicariously, — occasioning increased action of the one emunctory as the action of the other is impaired or obstructed, and subsequently very serious changes, both of the blood and of vital organs and parts, if the impaired or suppressed function be not restored.

61. The most serious and rapid derangements are produced in the circulating fluids, and consecutively in other parts of the economy, by impeded or obstructed function of the kidneys. In all lesions of these organs, especially in that which is called "Bright's disease," very important changes take place in the circulation; and, owing to these, further changes are produced in distant and different parts of the economy: the heart and the liver, the mucous and serous membranes, owing to the state of the blood, and more particularly to

the circulation of effete or injurious elements in it, become irritated; and organic changes, especially asthenic or spreading inflammation, the exudation of lymph, and more frequently of a serous or albuminous fluid, take place on the surfaces of these organs and of these membranes.

62. In connection with disorder of the digestive organs, we very frequently find the appearance of the skin more or less changed, even independently of the actual existence of jaundice. It would appear that, when the liver is torpid or inactive, or when affections of the liver are connected with disorder of the stomach, or of the spleen, or of the bowels, that the blood becomes more or less impure, or even deficient in red globules; and, consequently, the external surface and the countenance are more or less sallow, lurid, or without the vital glow of health. The liver performs not only secreting but excreting functions; it eliminates certain elements from the circulation, which, if allowed to remain, would produce more or less disorder: it thus depurates the blood to some extent; and hence we find that, in torpid affections of the liver, these elements accumulate in the blood, and, independently of true jaundice, produce slight pseudo-jaundice, or a lurid state of the skin and countenance, which is attributable to the impaired excretion of materials, which usually contribute to the formation of bile. But in cases of jaundice, where the obstruction is more serious, owing to the excretion of bile from the liver being impeded or prevented; or to the presence of calculi in the ducts, or in the gall-bladder; or to numerous organic changes that take place in the organ, there are certain constituents of the bile absorbed into the circulation, and certain of these more abundantly in some cases than in others. In some instances the colouring matter only is present, whilst, in others, the resinous portion of the bile, or the *bilin* of modern chemists, is carried into the circulation. It is very rarely that bile can be detected in the blood, but it has been detected in the urine; and we may therefore infer that it must have passed through the circulation before it arrived there, and that the kidneys, by the active discharge of their functions, have carried it out before it could accumulate in the blood so as to enable the chemist to detect it by the taste of the blood, or by the usual tests. I have already adverted to the effect of congestion, or interrupted circulation in the liver, on the abdominal organs generally, especially upon the digestive canal. I believe that this morbid association is not sufficiently attended to, particularly in respect of the diseases most prevalent in malarious and warm climates, and in fevers and disorders of the bowels in temperate countries; but my limits prevent me from pursuing this topic any further at this place.

63. ii. The Sympathy between the Digestive Organs and the Functions of the Heart and Lungs, owing to the media of association above described, is so marked, that disorder of any one of these organs naturally produces a reciprocative disorder in the other organs. Thus, increased excitement of the nervous system occasions excitement of the vascular system; and exhaustion or debility of the organic nervous system produces a similar state of all the organs which this system actuates. It may be considered an axiom, that increased excitement, or its opposite, namely, exhaustion or debility, however produced, is attended by a co-ordinate grade of such state, in the several vital organs. So obviously is this the case, that it is unnecessary to enlarge upon it.

64. *A. By contiguity of position*, the digestive, circulating, and respiratory organs are often very materially affected. Distension of the stomach or alimentary canal mechanically impedes the function of the other organs, and heightens inflammatory or structural lesions. Hence arises a deranged state of the circulation and of respiration in individuals in whom the nervous energy is weak, and where the contractile power of the parietes of the heart is to a certain extent weakened also. The contractile actions of the heart are much influenced by the distension of contiguous viscera. Flatus distending the stomach, and rising to the œsophagus, often produces intermittent or irregular pulse and various consecutive phenomena. This is frequently seen in cases of flatulency of the digestive organs. Very serious affections supervene in the case of hysterical and nervous patients, where the flatus rises up in the form of globus hystericus, producing inordinate distension of the œsophagus, with spasm above or below, or both above and below, the seat of this distension. The phenomena remarked in hysteria, in colic, and in flatulent distensions of the colon, may further illustrate the influence of mechanical distensions of parts of the digestive canal upon the functions of the heart and lungs; and hence it is, when the nervous and muscular powers of the heart are impaired, or when the vital expansive power of the lungs is weakened, that flatulent distentions of the stomach or of the colon increase the mischief. The number of morbid sympathies that I shall have to mention in the confined space to which I am limited, prevents me from illustrating fully this subject.

65. *B.* In considering the relation of the circulating and respiratory functions, it is unnecessary to do more than to notice the very great influence which the latter exert upon the former; the remarkable changes produced by the atmosphere during respiration, and the advantages that acrue from respiring pure air, not only in promoting a normal state of the blood, but in strengthening the locomotive functions. Air and exercise are the best restoratives that we possess — the principal tonics that we can employ in removing disorder. Those medicinal tonics which are frequently substituted for these, owing either to the circumstances of the case, or to the views of the physician, are generally more or less stimulants also, and may be injurious, and indeed are often hurtful, when injudiciously employed. But when the patient can have change of air, — when he is able to undergo a change, and can be duly exposed to the air and to the sun's influence, and more especially when he can take sufficient exercise in the air, — due assimilation of the food, healthy changes in the blood by the respiratory organs and cutaneous surface, and the development of nervous and vital energies, are the usual results.

66. *C.* I need only briefly refer to the intimate sympathy between the *digestive and the respiratory functions, surfaces, and organs.* It rarely occurs that the respiratory mucous surface is much affected without the digestive mucous surface being also more or less disordered, or that the latter is

seriously deranged without some disorder or susceptibility of disorder being manifested by the former, the association being clearly referable to the nervous system in the more immediate effects, and to the vascular system in the progress of the disorder. But affections of the mucous or villous surfaces of these distinct organs, although often thus appearing in succession — the one arising or depending upon the other — often also occur contemporaneously and co-ordinately. This form of association frequently is the result of endemic causes, and of epidemic influences; the morbid impression of these causes often extending rapidly, and manifesting its effect upon the digestive organs soon after it has acted upon the respiratory functions. Catarrhs, influenzas, hooping-cough, and other epidemic disorders which proceed from or are influenced by the states or vicissitudes of the atmosphere, and prevail at certain seasons, especially manifest this association; and those more formidable epidemics which arise from an atmospheric contamination, caused by the emanations proceeding from the sick, or from numbers of living creatures confined in a limited space, or from dead vegetable and animal matter, evince the same association, although in a much more remarkable manner, and are greatly heightened by contamination of the fluids and soft solids of the body.

67. When the atmosphere contains only a small or moderate amount of malaria, or of animal emanations, or a quantity insufficient to contaminate it to a pestilential extent, or even to cause agues or remittents, then disorders of the digestive organs, associated with affections of the respiratory and circulating functions, frequently result. In large towns and cities, especially where a humid and close air is more or less contaminated with animal exhalations, the prevailing disorders of the digestive organs are very often associated with affections of the respiratory organs, more particularly with chronic or asthenic bronchitis, or with congested states of the lungs. This association is most frequent amongst the children of the poor; either affection predominating over or masking the other, owing to the intensity or combination of the causes.

68. Whether those causes affect children, adults, or the aged — more especially if the more ordinary physical conditions and vicissitudes of the atmosphere have added to them, animal emanations, putrid effluvia, and insufficient ventilation — the effects produced seldom consist of a simple or specific state of disease, but of an association of maladies; one or two assuming a more distinct or prominent form, according to the intensity of the efficient agent, to the nature of concurring influences, and to the state or predisposition of the patient's constitution. This complication becomes still greater, and much more serious, if these causes not only injuriously impress the organic or ganglial nervous system, but also, either through the medium of this system, or still more directly, contaminate the circulating fluids, — the contamination arising both from the impairment of depurating processes performed by the various emunctories, and from the passage of injurious agents into the blood during respiration.

69. Physicians who observe closely the morbid conditions constantly coming before them must have remarked, especially in large towns, where numerous injurious agents are in almost continued operation, and amongst persons who attend the least to the healthy states of the digestive and excreting functions, that when the digestive functions are much impaired, or when the digestive mucous surface presents those phenomena which may rationally be referred to chronic irritation, numerous associated disorders soon present themselves. The hepatic functions are deranged; often also the bowels are affected; and ultimately even the excretions from the skin and kidneys betray more or less disorder. The results of these morbid conditions, or more frequently the contemporaneous mischiefs, comprise changes in the nervous and vascular systems — functional changes in the organic nervous system, being followed by impairment of the excreting or depurating actions, and this impairment by an altered state of the blood itself; this last acting upon the former, and aggravating them. As long as vital power or resistance to the injurious agents is not entirely overthrown, various vicissitudes occur in the course of functional disorder, in the states which the several organs implicated present, and in the consequences which accrue in respect of each, under the influence of either aided or unaided vitality. But not unfrequently various serious phenomena, threatening the duration of life, appear, owing to contingent causes and morbid predispositions. It is thus we so frequently observe in practice, among persons who have been previously out of health, who have been intemperate and dissipated, who have suffered from functional disorders of the stomach, or liver, or bowels, or kidneys, or from an association of two or more of these, that far more serious maladies are superinduced; that, owing to the morbid state of the blood from impaired action of the emunctories, and to the disposition of irritation or inflammation of membranous parts to spread in these circumstances, erysipelas thus often appears in the seat of an abrasion or injury, especially in certain atmospheric conditions; that the pharynx or fauces, or both, sometimes with their connected glands, become affected with a spreading or asthenic inflammation, that the lesion, owing to continuity of texture and weakened vital resistance, proceeds either along the œsophagus to the stomach, or, what is still worse, it extends from the pharynx to the epiglottis, or even down the trachea, causing distressing paroxysms of cough, or threatening, and even causing suffocation from closure of the glottis, or fatal conjestion of the lungs. The lesion, thus first manifesting itself in the fauces or pharynx, may actually even commence in the stomach, and extend upwards along the œsophagus to the pharynx, without the œsophageal affection being either recognised or prominently developed, until the more sensitive and susceptible pharynx is reached. Indeed, it is not unfrequently observed, that acrid eructations from a dyspeptic stomach, or owing to a state of gastro-enteric irritation, excite an asthenic form of inflammation of the pharynx and posterior fauces, which sometimes spreads in one or other of the directions just pointed out, either involving merely, or chiefly, the upper portion of the œsophagus, or implicating more especially the epiglottis and larynx, or even also the trachea. These are some of the more serious or extreme morbid associations observed between the digestive and

respiratory organs; but others of a slighter grade are much more common; these are stomach cough, the *catarrhus stomachicus*, *catarrhus saburralis*, &c. of older writers; the association of gastro-intestinal irritation with catarrah, or with bronchitis, or other affections of collatitious or even of distant viscera, &c.

70. iii. THE SYMPATHIES OF THE DIGESTIVE ORGANS WITH THE BRAIN AND WITH THE ORGANS OF SENSE, AND OF THE LATTER WITH THE FORMER, are sufficiently manifest. But it is very frequently by no means easy, when the associated morbid conditions come before us in practice, to determine the organ primarily affected, and most probably the source or centre of the associated affections.—*A*. The *media* of morbid association in many of these complications are obviously, and primarily, the ganglial and the cerebo-spinal nervous systems, as already explained. But cases are not few, which acknowledge, not only these media, but also the vascular system—a morbid condition of the circulating fluids. When the blood is loaded with effete matters, or is not sufficiently acted upon in the liver, or changed by the several depurating organs, or by the lungs, or by the kidneys and skin, it affects the brain, producing, more or less, disorder according to the nature of the existing impurity. This state of the blood, in its slighter grades, may give rise only to lassitude, or to a state of apathy, or more or less lethargy. It is not improbable that the lethargy observed after a full meal is partly caused by the passage of chyle into the blood, which, to a certain extent, changes the state of this fluid, and affects the brain. When the blood is more seriously altered, when it is affected by obstruction of the excretion of bile, and when it is still more remarkably changed, both in quantity and quality, by disease of the kidneys, the effect upon the brain is often serious, and in the latter case, even fatal. In more common cases and circumstances, and in those of much more frequent occurrence, impaired digestion, is followed by imperfect assimilation of the chyle; this latter, more or less, affects the blood, and the state of the blood thus produced often affects the sensibility of the brain and nervous system, either temporarily, or at intervals, even before the actions of the emunctories are manifestly impeded or otherwise disordered.

71. *B. The organs of sense* often sympathise with disorders of the digestive organs. Those of sight, hearing, smell and taste, are severally weakened or rendered more susceptible of impressions, in some instances, or less so in others, when the functions of digestion are imperfectly performed, owing to impairment of the ganglial nervous power, actuating the digestive organs, having extended to the nerves and organs of sense, with which the ganglial nerves are intimately connected, especially as respects the cerebral and cervical ganglia and plexuses. Nor should it be overlooked, that, when the influence or power of the ganglial nerves, which supply the vessels and membranes secreting the fluids which enable the nerves of sense to perform their functions, is insufficiently exerted or is depressed, these fluids are then insufficiently secreted, the membranes imperfectly nourished; and consequently, the sensorial surfaces, and the terminations of the nerves of sense in these surfaces, are not in a fit state to receive impressions, and are incapable of transmitting them so vividly and perfectly as if the organic or ganglial nervous system duly discharged its duty.

72. iv. THE LOCOMOTIVE APPARATUS SYMPATHISES MORE OR LESS WITH THE STATE OF THE DIGESTIVE AND ASSIMILATING ORGANS.—The former, however, may not be much affected when the latter are slightly disordered; but if the disorder of the digestive functions continue long, or if it be great,—if the organic nervous or vital energy of these organs be much reduced or exhausted by previous excitement, and, still more remarkably, if this depression of vital energy have, owing to its continuance or severity, given rise to a morbid condition of the circulating fluids, or to an excrementitial plethora, the locomotive power always suffers more or less. The joints are particularly disposed to manifest disorder when the digestive and assimilating functions are imperfectly performed, and the secreting apparatus of the joints then suffers more especially. When urea, or its elements, accumulate in the blood, or, indeed, when either these or other excrementitial elements accumulate in the circulation, or when mal-assimilated or other injurious matters are conveyed into the circulating fluids, and more particularly when the functions of the liver, of the bowels, and of the kidneys, betray disorder, the joints then often become seriously affected. If the history of various diseases affecting the joints be carefully traced, and their several morbid relations observed, it will very often be found that impaired digestion and assimilating function, as well as impeded excretion, has long preceded, and often still more remarkably attends, the affection of the joint. *Gout* furnishes the most remarkable instance of this morbid association; but rheumatism also displays it. Other disorders hereafter to be mentioned, as hysteria, also betray the connection between them and affections of both the joints and the digestive organs. The sympathy in these mordid associations is obviously dependent upon the ganglial nervous system and its connection with the sensory spinal nerves, and is increased and rendered more permanent, especially in gout, by changes in the circulating fluids, and by imperfect elimination of effete materials, or of the ultimate products of assimilation and animalization, by the several emunctories.

73. v. THE SYMPATHIES OF THE REPRODUCTIVE ORGANS WITH THE FUNCTIONS OF DIGESTION are often obvious. They will be more particularly noticed in the sequel; but I may now observe that debility of the latter often deranges the former, or predisposes to most of the disorders to which the reproductive organs, especially of the female, are liable. There is, however, a mutual action and reaction between disordered conditions of these organs and the organs of digestion; and even in these cases, which occur so frequently in practice, where the association of these disorders is very remarkable, it is often very difficult to determine which of these organs is primarily in fault. Many cases of chlorosis, of amenorrhœa or dysmenorrhœa, or even of menstrual obstruction, of hysteria, and of leucorrhœa, are more or less dependent upon disordered digestion and assimilation, whilst others originate, as will be mentioned hereafter, very differently, and consecutively derange the digestive functions.

74. V. THE SYMPATHETIC AND SYMPTOMATIC PHENOMENA CONNECTED WITH THE CIRCULATING AND RESPIRATORY FUNCTIONS.—I shall here offer some observations on the importance of considering morbid action with reference to the state of the circulating fluids.—i. Having discussed, as fully as my limits permit, the nervous connections giving rise to numerous and obvious sympathies, I shall now take a general view of *alterations of the blood itself*, as being productive of diseased action, either in succession or contemporaneously, in two or more distinct or distant organs, or more or less throughout the frame. In disorders of the circulating fluids, particularly of the blood, the most extensive and serious associations of disease often arise to which the animal economy is liable.

75. The circulating and respiratory functions are intimately associated with each other, not only by nervous and vascular connections, but also by position and by the nature of the functions themselves; a certain amount of change of the constituent elements of the blood always taking place during respiration, and also a reaction of the blood on the respiratory organs, and on the heart and blood-vessels. These vital functions, although presenting more or less prominent relations to disorders of other or distant organs, are often, owing to these circumstances, jointly and correlatively the affected.

76. *A.* Before I take a cursory view of the results of chemical researches into the morbid changes of the blood, I shall briefly notice the *healthy composition of this fluid.* From a series of analyses, SIMON considered that 1000 parts of healthy blood consist of $795\frac{3}{10}$ of water, and about $204\frac{3}{10}$ of solid residue. In the latter there are $2\frac{1}{10}$ of fibrin; $2\frac{3}{10}$ of fat; $76\frac{6}{10}$ of albumen; $109\frac{3}{10}$ of hæmato-globulin; and about 12 parts of salts and extractive matter. These being the mean proportions in health, it has been attempted to establish the deviations which take place in these constituents in disease. A number of chemists and physiologists have performed experiments on the blood both in health and in disease, but there is a considerable difference between the results at which they have arrived; still there is sufficient agreement to warrant the importance of attention being devoted to subject.

77. In *disease*, the water varies from 888 parts in 1000 to 750 parts; the solid residue from 250 to 112. Of the different matters forming the solid residue, fibrine varies from $9\frac{1}{10}$ to a trace merely; the fat, from $4\frac{3}{10}$ to only $\frac{7}{10}$; the albumen from 131 to $55\frac{1}{10}$; the hæmato-globulin, from $115\frac{4}{10}$ to $31\frac{2}{10}$; the extractive matter and salts from $16\frac{5}{10}$ to $7\frac{6}{10}$; these results thus showing a very considerable variation in the quantities of the several constituents of the blood in disease.

78. *Healthy blood*, again, according to LECANU, consists of 790 parts in each 1000 of water, and 210 parts of solid residue. Of the latter, 3 parts consist of fibrin, 127 of blood-corpuscles, 72 of albumen, and 8 of extractive matter and salts, or what he calls inorganic matter. According to ANDRAL and GAVARRET, taking this to be the standard of health, these constituents vary in *disease* as follows:—The water from 915 parts in each 1000, to 725; the solid residue from 275 to 85. Of the latter, the fibrin varies from $10\frac{5}{10}$ to $\frac{9}{10}$ only; the blood-corpuscles from 185 to 21; the albumen from 114 to 57.

79. It must be evident that the blood which is taken from young, healthy, or robust persons, especially those of the sanguine temperament and the phlogistic diathesis, will exhibit a large proportion of blood-globules or corpuscles, and also of fibrin; whilst the blood of leuco-phlegmatic or of chlorotic and anæmied persons will furnish the smallest proportion of these constituents and the largest quantity of water. When the blood is removed, or being removed, from a vein, and especially as it circulates in the vessels, there certainly exists in it more or less carbonic acid, although the exact quantity — probably of various amount with the varying state of the system — can hardly be shown by experiment. It is, doubtless, given off so immediately, on being removed from a vein, that its exact quantity scarcely admits of demonstration. The blood also presents a certain *odour*, either independently of, or connected with, the halitus, or vapour, or carbonic acid, which it exhales, when drawn from a vein or artery; and this odour is very remarkable in malignant and infectious diseases, and especially in pestilential fevers.

80. It is very manifest that the blood, when circulating in the system, possesses a vital endowment, derived from the organic nervous influence, bestowed by means of the organic nerves on the blood-vessels, and on the tissues and parenchyma of organs through which the blood circulates. This vitality of the circulating fluids, thus derived, may be traced in the chyle, and is manifested by this fluid as soon as it begins to circulate in the lacteals, inasmuch as it presents analogous changes to those evinced by the blood itself, as respects coagulation, when removed from these vessels.

81. The globules of the chyle present the first appearances of organisation; or, in other words, assimilation and organisation, commencing in the chyle and manifesting themselves in the conformation of the globules formed in this fluid, proceed as the chyle passes through the glands, becoming more distinct and perfect as the chyle advances and reaches the ducts conveying it into the blood. The globules of the chyle, being thus more perfect and more numerous the nearer they approach the venous circulation, and after having passed through lacteal glands and having derived some vitality from the vessels and glands through which they have circulated, possess in consequence a vital relation with these parts, tending, not merely to promote their circulation onwards to the blood-vessels, but preparing them also for further changes, — for a more advanced grade of organisation, when they have reached this goal, and for the assumption of the character of perfect blood-globules.* It is not at all im-

---

* Since this article was written, the researches of MR. WHARTON JONES, on the blood, have been published in the Philosophical Transactions. From these it would appear that the chyle-corpuscles pass through the following phases of development before or by the time of their reaching the venous circulation: — *First phase*, that of granular cell, the first stage of this phase being coarsely granular, the second stage finely granular: *second phase*, that of nucleated cell, the first stage of this phase being uncoloured, the second being coloured. He considers that the *nucleated cell*, in its second or coloured stage, passes into the *red corpuscle*, in the fully-formed blood of man and the mammalia, and that the nucleated cell is thus changed into the fully-formed

probable that the assimilation or the organisation of the globules of the chyle, as well as of those lymph-globules, circulating in the lymphatics, either originates in, or is advanced by, the glands in the course of both lacteals and lymphatics; and it may also be inferred that the further organisation of the lymph-globules — both those carried into the blood from the lacteals, and those from the lymphatics — or their conversion into the fully-formed red blood-corpuscles, is owing to the vital operation of those glands which are not provided with excreting ducts; as the spleen, the supra-renal glands, and the thymus, and probably also of the liver. The facts long and frequently remarked by me of anæmia, or deficiency of red-globules, being always the consequence of torpor, enlargement, or other disease of the spleen or liver, favour this view of the influence of these viscera in the assimilation or development of the chyle and lymph-globules into red blood-globules. It may therefore be inferred, from the organisation of the lacteal and lymphatic vessels and glands, and of those non-excreting glands just mentioned — from the circumstance of these organs being abundantly provided with ganglial nerves, blood-vessels, and absorbents, that the fluids carried to, and circulating through them, undergo an assimilation, and that this assimilation amounts to a progressively increasing organisation of the globular constituents of these fluids, — this being the function of the organs now referred to.

82. Organisation thus commencing in the chyle or lymph, as respects the perpetuation of the individual animal, it must necessarily follow that these fluids participate in the vitality existing in the vessels and organs through which they circulate. This vital endowment, whether existing in the fluids as a simple emanation from the containing structures, or actuating them more efficiently through the medium of their globules, is evidently concerned in the phenomena displayed by these fluids, as well as by the blood when removed from the vessels, as I contended many years ago; the changes observed to take place in these fluids, and more especially their coagulation, being the consequences chiefly of the loss of the vitality, or of the organic nervous influence or emanation endowing these fluids. If, therefore, it be admitted — and it cannot be rationally disputed, or with a due recognition of healthy and of morbid phenomena — that the circulating fluids are thus vitally endowed, it must necessarily follow that this endowment is dependent upon, and co-ordinate with, the vitality or the organic nervous energy of the frame; and, further, that whatever contaminates these fluids must necessarily co-ordinately affect the vitality of the frame through which the contaminated fluids circulate.

83. *B.* Contamination of the circulating fluids may commence — 1st, in the lacteals, through the medium of the digestive canal; — 2nd, in the lungs, through the medium of the respiratory surfaces; — 3rd, in any part of the external surface of the body; — and, 4th, in any part or tissue of the frame, by a self-contamination; and, thus originating, the contamination may manifest itself either generally, coëtaneously, and co-ordinately throughout the frame; or prominently, and especially upon particular organs or parts, other organs or parts betraying comparatively but little disturbance. Of these sources of contamination I shall take a very brief and passing view, as far as they may elucidate the associations of disease.

84. 1st. If the lacteals communicate with veins concurring to form the portal circulation, as some assert, and believe that they have demonstrated, and whether this communication take place before or after they have passed through their glands, or does not take place at all, the injurious influence of a contaminated or unwholesome chyle upon the circulation, and the organs through which it passes, will readily be admitted. If the contaminated chyle passes more directly into the blood circulating to the portal vessels, and without pursuing the longer route to the general venous circulation, it must necessarily follow that the functions and even the organisation of the liver and its vessels, will be placed in great jeopardy; and it may be further inferred that, whatever may be the route which the chyle takes, the globules will not undergo their wonted healthy advances towards complete organisation either before they reach the blood, or after they have entered into it. It is even very probable that the blood, thus abounding in an unwholesome or contaminated chyle, and with imperfectly assimilated or organised chyle or lymph-globules, will disorder the functions, and ultimately the organisation of those structures and organs more immediately concerned in perfecting these globules, or transmuting them into perfect red blood-globules.

85. 2d. The second channel of contamination, or that through the respiratory organs, hardly requires any notice, it being so obviously one through which the most injurious agents are conveyed into the blood itself, thereby infecting or contaminating this fluid, and, through its medium, either remote parts, with which the particular agent may have especial relations, or the whole frame. It is through the respiratory surfaces that the emanations from numerous sources infect the system — effluvia from the soil and its productions, and exhalations from dead animal matters and from diseased bodies; and although this source of contamination and infection is the most obvious to every one who is capable of speculating respecting the causation of disease, especially when considered in connection with the functions of the respiratory organs, yet it has been most frequently overlooked or insufficiently estimated. The blood is affected not only by the physical constitution of the air as respects temperature, humidity, electrical conditions, but also by those foreign gases, vapours, and emanations from living and dead organised bodies existing on the earth's surface. These severally, sometimes variously associated, affect both the vital conditions of the lungs — the organic nervous energy of the organ — and thus directly, as well as indirectly, modify the changes which take place in the blood circulating through the lungs, or otherwise contaminate this fluid in modes more or less specially related to the nature of the causes or agents which operate through this channel. (See art. Infection.)

86. 3d. The *third* or cutaneous channel of con-

---

red blood-corpuscle, by the cellæform nucleus of the nucleated cell being set free by the bursting of the cell itself, the nucleus having become filled and red by the secretion of globuline and colouring matter into its interior.

tamination is certainly less frequently influential than those already passed in review. Still all the physical conditions of the atmosphere, and all the foreign gases, vapours, and emanations floating in the air, which so readily and injuriously invade the system through the respiratory organs, also affect the functions of the skin, and thereby the conditions of the blood, and the states of the several internal viscera, and more particularly of the other excreting organs. The most serious contaminations of the circulating fluids, and of adjoining parts produced through the medium of the cutaneous surface, arise from the septic influence of a foul or infected air upon this surface when it is punctured, abraded, or deprived of that protection at any one point which the cuticle or epithelium is destined to afford, or when mucous surfaces, and especially serous surfaces, are exposed to this cause. In these circumstances, the skin itself, in some instances; the lymphatics or veins, or both, in other cases; or the cellular tissue, in some; and even all these, in a few, are seriously affected, and ultimately the blood itself is more or less contaminated; remote parts, and even the whole frame, becoming thereby implicated in the foul, septic, and disorganizing process thus commenced and most rapidly propagated. And here I may advert to the influence of the air in many situations, but more especially in towns and ill-ventilated places and houses, in extending disease originating in, or chiefly consisting of, lesion of the cutaneous surface; and the insufficient attention usually paid in practice to a due protection of exposed points of the cutaneous surface from the influence of the air, and to the exclusion of this fluid from deep-seated injuries or diseases. Nature provides a spontaneous remedy against the endosmosis or imbibition of infectious or contaminating agents existing in the air, by throwing out lymph, which, by coagulating, protects the exposed or injured point or surface; but the powers of life, as manifested by the capillary system, are not always adequate to this effect, and the consequences are the imbibition of septic matters, which contaminate the surrounding tissues and the fluids taken up by the absorbing vessels, and occasion a spreading, or asthenic, or diffusive inflammation of these vessels, of the lymphatic glands, and of the adjoining cellular tissue, the most manifest changes in the blood itself, and not infrequently extensive disorganization of remote organs and parts.

87. The changes thus arising in, and propagated from, the third channel of contamination, sometimes equally originate in and are propagated from deep-seated or internal parts, through the medium of circulating fluids and vessels, to distant situations, where they may be manifested only or chiefly. In the articles ABSCESS, ABSORPTION, BLOOD, DISEASE, and INFECTION, I have fully shown the manner in which morbid secretions or other depositions may contaminate not only the adjoining tissues, but also the circulating fluids, and ultimately occasion disorganization, and the formation of puriform or other morbid collections or lesions in distant organs or parts. I have so fully enlarged, in the places just indicated, on the views and doctrines which these consecutive lesions involve, that I need not allude to them at this place, more especially as they have been adopted by subsequent and recent writers; not always, however, with a due acknowledgment of the original sources.

88. It having thus been shown that the formation and perfection of the chyle and lymph-globules are probably owing to the vital influence of the vessels and glands through which they circulate, and that the metamorphosis of these globules to perfect red blood-globules is due to the functions of the glands not possessing excreting ducts, and of the liver, it necessarily follows that the absorption or passage of injurious, imperfectly assimilated, or other morbid matters into this fluid, must occasion disease in the organs more especially devoted to these functions; whilst impaired function of these organs, or structural lesions of them, must also impede or interrupt the progressive changes of these globules, and the formation of perfect blood-globules; the conditions of the blood itself becoming thus more or less imperfect or diseased, and incapable of undergoing in the lungs those changes which are requisise to the due nutrition of the frame, and healthy condition of the several viscera.

89. What the exact conformation of the several globules existing in the chyle, lpmph, and blood, may be, is not, perhaps, yet fully determined, or, at least, admitted, by the numerous observers who have attempted to investigate the subject. But it may, at least, be inferred that these globules undergo a progressive organisation, and that the organs already mentioned are instrumental in producing it; but it should likewise be considered that the changes produced in the blood in the lungs and in the general circulation, as well as the influence of the air upon the blood, are also more or less intimately connected with the perfection of these globules, as well as with whatever alterations they may undergo subsequently to their full development. Neither microscopic nor speculative physiologists have shown the nature of the relation existing between the atmospheric elements and the blood-globules and other constituents of the blood, so as to explain the phenomena of nutrition and the sustentation of nervous or vital energy. Certain of the more manifest phenomena have been remarked, but not accurately traced or irrefragably demonstrated. It may be asserted that the oxygen of the air combines with the blood-globules, and gives rise to changes necessary to nutrition, to nervous endowment, and even to the circulation of the blood itself. But it is quite as difficult to prove as to disprove this proposition, with the subordinate relations between these globules and the several general systems and special organs which this proposition involves.

90. At the present day, the chemical changes which occur in the blood have become subjects of discussion, and too generally with an entire neglect of those alterations which arise from the states of vital power. The former can seldom be recognised in practice, and are often unappreciable even in the most dangerous diseases; whilst the latter are generally the most manifest and characteristic, and present themselves in this manner to the unaided senses. To these latter, therefore, our attention should be directed, inasmuch as they indicate not merely the states of the blood itself, as respects its more important constituents, but also the conditions of organic nervous or vital power—conditions of the utmost importance to be correctly estimated by the physician. It should

not, moreover, be overlooked that even the most gross and evident chemical changes are merely the results of vital power and vascular action controlling the changes which are imputed to chemical affinities; but which are truly the results of a vital chemistry, or of affinities controlled by vital forces. Whatever may be the nature of the intimate chemical changes which take place in the blood, either in the lungs, or in any other organ, there is every reason to assert, that these changes would not result, if the organic nervous influence were removed from the organ in which they take place in health; and further, a close observation of the causation of the changes observed in the blood during disease, leaves me to infer, that most of those changes are more or less influenced or produced by conditions of nervous energy or vital power, chemical action or affinity having nothing to do with the matter, further than in favouring the combinations of alkaline bases with oxygen, and of these or other compounds with acids; and those combinations even are favoured or controlled by the vital powers.

91. In speculating upon the changes taking place in the blood, the chief places are assigned, as agents, to the oxygen of the air, and to the carbonic acid or its constituents, as existing in the blood. What change, if any, may be affected by the nitrogen of the atmosphere, is not ascertained. It is supposed that azote produces little or no alteration of the blood; yet it is not unlikely that, although the amount may not be appreciated or appreciable — at least there is no admission of appreciation by chemists — there is, nevertheless, a change produced by it, both on the fluids which are carried into, and on the fluids which circulate in the system.

92. *C.* In the various speculations on the changes occurring in the blood in health and disease, until the appearance of the article Blood in this work (in 1832), and to which article some more recent writers have been much more indebted than they are willing to admit, the alterations of the blood —*the pathology of the blood*—have been very imperfectly and worse than superficially treated of. And whilst physiologists and pathologists have directed some attention to the processes of sanguifaction, they have altogether neglected to show how *the destruction or waste of the hæmato-globuline or red corpuscles takes place*, so as to prevent, during assimilation and nutrition, an exuberance—a morbid plethora—of this constituent of the circulating fluid from occurring.—*a.* A topic which has not been considered with reference to the healthy state can hardly be supposed to have been investigated in connection with disease. But it cannot be unreasonable to infer, that in health the waste may proceed from the following sources: — 1st, from a partial vital decomposition and conversion of the hæmato-globuline or red-corpuscles to supply by nutrition the waste of the several tissues; 2nd. from the conversion of a portion of the globules in the portal vessels into bile; 3rd, from the action of the mucous follicles, especially of those seated in the lower portion of the small and in the whole of the large bowels, upon the blood conveyed to them; 4th, from the operation of the other emunctories, although in a much less degree, especially the kidneys and skin; the epithelium cells, thrown off by these, being transformed blood-globules, either before or after they had acquired their colouring matter or property; and 5th, from the elaboration of the sexual fluids and discharges in both sexes.

93. *b. During disease*, the waste of the hæmato-globuline or red-corpuscles may be either hastened, increased, or impeded, more rarely the latter. It may be hastened or *increased* — 1st, by insufficient assimilation owing to impaired organic nervous or vital power; 2nd, by morbidly increased action of the liver; 3rd, by increased action or elimination of the emunctories, especially of the intestinal follicles and surface of the skin and of the kidneys, owing to the impaired vital endowment of the globules and crasis of the blood having provided these emunctories with an increased pabulum, or material whereby their actions are augmented; and 4th, by the morbid or increased action of the sexual organs in either sex. Owing to the excessive action of these sources of waste, the blood may become poor or deficient in hæmato-globuline and red corpuscles; and accordingly we find, not only where assimilation is deficient, owing either to inanition or impaired vital power, but also where either of these sources becomes inordinate for any continuance, that a poor state of the blood or anæmia takes place. In low or adynamic fevers, in diarrhœa or dysentery, in some affections of the kidneys, in leucorrhœa, in self-pollution, and in excessive sexual intercourses, in acute rheumatism, especially when attended by excessive perspiration, this state of the blood generally supervenes. As respects rheumatism, this result escaped the observation of previous writers, until I mentioned it when treating of this disease. (See art. Rheumatism, §§ 84, *et seq.*)

94. *D.* During the process of circulation, in consequence of the changes that take place in the chyle and blood-globules, of the absorption of chyle from the digestive canal, and of effete matters from the several tissues, considerable changes must necessarily take place in the blood, and, as the result of these, numerous phenomena must be produced in, and evinced by, the excreting organs — the skin, the lungs, the liver, the intestinal canal, and the kidneys. There appears to be a very intimate sympathy between the functions of these organs. Many years ago I had an opportunity of putting that subject to the test. In 1814 and 1815, I was engaged in a number of experiments on the effects of temperature upon respiration and the blood in different states of the system, and the results of those experiments were afterwards published. Subsequently when visiting an unhealthy and warm climate, I had an opportunity of observing the changes there produced in the air by the respiration of individuals of different races, and found that, during cold states of the atmosphere, and soon after digestion, the greatest changes took place in the blood,—the greatest consumption of oxygen, and the greatest amount of carbonic acid then appearing in the expired air; while in a very warm state of the atmosphere, and several hours after a meal, when the vital powers are depressed, the smallest amount of oxygen was consumed, and of carbonic acid existed in the expired air; and these latter effects were most manifest when the system was subjected to the influence of malaria. It was also further considered, that the cutaneous function was, to a certain extent, supplemental to the function of respiration; that, in

fact, as observed in some of the lower animals, the cutaneous function is, to a considerable degree, one of respiration. This, even in the human species, appears to be the case, more especially as regards negroes. I made several experiments, in a very warm climate, on the respiratory functions of this race, and found that the quantity of carbonic acid given off from the lungs, in this variety of the species, was almost one-third less than that given off by the lungs of an European of the same size, and at the same temperature; whilst, in the former, the changes taking place on the cutaneous surface were greater in degree, and more extensive in kind, than in the latter, — the supplemental respiratory function of the skin of the negro being not only more remarkable as regarded the formation of carbonic acid and the exhalation of watery vapour, but also peculiar as respected the amount of animal matter and effluvium impregnating the exhaled vapour and watery fluid.

95. I attempted at that time to account for the prevalence of fevers, and disorders of the biliary functions, &c., so prevalent among Europeans migrating to a warm climate, by the state of the blood consequent upon the diminished changes produced by the air on the blood, and by the superabundance of the elements from which bile is formed existing in the circulation; the liver thus for a time performing a vicarious action to the lungs, — the deficient function of the lungs, in an European in warm climates, being made up by the greater activity of the liver. However, this exists in individuals only for some time after they arrive in a warm climate, and very frequently it is not so remarkable after a year's residence there. Active exercise also in a warm climate, by increasing the functions of respiration and cutaneous exhalation, remarkably relieves the increased function of the liver, and prevents many of the consequences of this disorder.

96. There is also a very intimate connection existing between the state of the blood and the depurating offices of the mucous surface of the intestines, especially of the large intestines. This surface, and more particularly the follicular glands, may be considered as eliminating from the blood, redundant or decomposed blood-globules (§ 92.), and much effete materials, and as thereby contributing, with the other emunctories, to the purity and healthy condition of this fluid. The connection subsisting between the functions of excreting viscera, not only as altering the condition of the blood, but also as affecting each other individually,—the influence which the state of one depurating function exerts upon the others, through the mediums of the blood, as well as through that of the organic nervous system, and the mutual and conjoint operation of all these functions, not merely in changing the physical appearances and constitution of the blood, and the states of vital influence, but also in occasioning structural alterations, are amongst the most important topics comprised by a rational system of pathology. Without due consideration being devoted to them, the morbid changes constituting the progressive periods of disease, the media of connection subsisting between affections of distant parts, and the passage of one alteration into another, cannot be traced; and the association of disease of one organ, with equal or even greater disease of another organ, cannot be explained, and neither anticipated nor guarded against in practice.

97. *E.* It is of great importance to the physician to observe closely the *physical appearances or sensible characters of the blood*, when removed from the subject of disease, both immediately upon and some time after its removal. It is hardly possible for him to devote his attention to the analysis or *chemical constitution* of this fluid, inasmuch as this requires considerable time and diversified experiments to arrive at satisfactory conclusions; and, besides, many of the changes observed are truly vital, or at least the results of departing vitality, and are either very imperfectly, or not at all, indicated by chemical analysis or tests, although frequently manifested by distinct physical characters. The physical appearances of the blood, when removed from the body during the life of the patient, are of the utmost importance, as indicating not only the conditions of this fluid *per se*, but also the states of vital power; and as furnishing the chief indications of cure. My limits will not admit of my noticing, otherwise than in very general terms, the principal alterations of the blood, which tend both to associate alterations of distant parts, and even to contaminate more or less the soft solids of the body. The perusal of what has been done by chemists, even down to the present day, to demonstrate the chemical changes of the blood, even in the advanced stages of disease, will furnish but little information which can be used practically, compared with attentive observation of the physical changes of this fluid. These latter changes I have fully described in another place (see article Blood), and therefore I shall not even briefly advert to them now, but merely notice two or three topics connected with the subject more immediately under consideration, some of which have not received sufficient attention from other writers.

98. *a.* Various changes as respects the *colour* of the blood, both at the time of removing it from the vein and afterwards, have been observed. The blood may present every shade of colour, from a pinkish hue, or a pale or florid red, to a deep red, or a brownish or dark red, or dark violet, or even to a brownish or black, or dark greenish hue. The first of these colours is observed chiefly in cases of anæmia; the latter of them in congestive diseases; and the last chiefly in pestilential or malignant maladies, or in cases of poisoning,—indicating not only a contaminated state of the blood, but also impaired organic nervous influence of the vessels and vital organs.

99. *b.* But it is not merely the colour of the blood, but also the rapidity and mode of its *coagulation*, and the *state of the coagulum*, that requires the attention of the physician. The relative proportions of coagulum and serum; the firmness, or the flaccidity or softness of the former; the presence of cupping of the coagulum, or of the buffy coat, and the thickness and density of the buff, are circumstances which will be duly estimated by him, as indications of organic nervous energy or excitement —of states of encreased vascular action and of vital resistance. He will, from these conditions of the blood, infer existing states of the whole vascular system, and of the organic nervous system as actuating the vascular—viewing these conditions as the results of the states of these; and whilst he estimates them all at their true value, he will not

attribute undue importance to any one condition apart from the rest. He will not, as in a case to which I was recently called, after taking away between thirty and forty ounces of blood, again take away nearly as much within a few hours, merely because the latter cupfuls of the former bleeding were cupped and buffed, and thus nearly destroy the patient; but experience will soon show him, if education have not taught him, that, in inflammatory affections of serous or fibrous tissues, and in diseases attended by vascular excitement, without loss of vital power or resistance, or infectious contamination of the blood, the fibrin continuing abundant, the coagulum may present these appearances to the last, and even although it may be relatively small to the amount of serum.

100. But, in different states of the organic nervous influence or vital power, and owing to these states either primarily or consecutively, the blood presents very opposite physical characters. It coagulates more rapidly and more imperfectly, or even hardly coagulates at all, or at least does not separate into any coagulum distinct from the serum. These characters are usually observed in depressed states of vital power and resistance, and in contaminated or poisoned conditions of the blood, and are owing either to absorption of contaminating and morbid matters, or to interrupted depuration by the several emunctories. In some malignant diseases characterised by extreme depression of vital energy, with a rapid state of the circulation, the change in the appearances of the blood has been most remarkable and sudden or speedy in its accession. In the worst form of puerperal fever—a disease which I have seen go on to a fatal issue within twenty-four hours from its accession, and for which blood-letting was often most improperly and fatally employed, because it had been recommended by some dangerous because ignorant writers — the blood has, in some instances to which I was called, subsequently to its abstraction, presented the appearance of a straw-coloured and very thin jelly, without any coagulum, the colouring matter being precipitated to the bottom of the vessel of a black hue, and in the manner of a powder which had been mechanically mixed in the fluid which had suspended it, and without the least cohesion between its particles. In these cases, as well as in some other maladies characterised by extreme depression of vital power, and a poisoned state of the blood, the coagulation is not only imperfect, but is of a peculiar kind; the colouring matter being detached from the other constituents of the blood almost as soon as the blood passes from the vein, the fibrinous elements forming a thin jelly with the serum of the blood. The small amount of vitality possessed by the blood in these cases, is lost immediately upon its abstraction from the body; and the fibrin, although it may exist in tolerable quantity, is incapable of contracting or adhering so as to form a coagulum, yet often uniting so loosely in the serum as to form a thin gelatinous mass.

101. *F.* The *quantity* of blood in the system has also a very important influence in associating diseases of distant organs or parts; and this influence becomes still greater and more general if the blood either abound in excrementitial elements, or be in any way poisoned or contaminated. The quantity of blood may be diminished as respects either the general amount, or the colouring constituents, or hæmato-globuline; and it may be deficient in a single organ. It is not unusual to observe in cases of general anæmia an irregular distribution of the blood, some organ or part experiencing an excess, whilst the diminution is still more remarkable in other parts. This is usually observed when, with anæmia, there exists local irritation, or excitement of the organic nervous influence of a particular organ. In this way distant parts often present consentaneous morbid phenomena, and the organ which has received to-day a more than proportionate supply of that blood which is deficient either in general amount, or in colouring matter, or in fibrin, or in all these together, may present on the morrow more than usual deficiency; and thus a new combination of disorders may arise. This is not unfrequently met with in nervous, susceptible, and hysterical persons, in whom the distribution of blood is always more or less under the control of the nervous system, more especially the ganglial.

102. If the influence of these states of the circulation be remarkable in associating disorders of distant parts, that produced by the opposite state, or too great fulness, is not the less so, more especially if the fulness be attended by an excess of effete or excrementitial elements. Vascular plethora, as long as the blood is duly changed by the emunctories, favours active determination to particular organs, especially to those liable to irritation or nervous excitement, — not infrequently also to acute inflammations and active hæmorrhages, according to the diathesis and the nature of exciting or concurring causes. But if excrementitial fulness supervene, owing to the imperfect discharge of some depurating function, as that of the kidneys, some distant organ is placed in great jeopardy, or effusion takes place in shut cavities, or in the cellular tissues. But these results may equally occur although the amount of blood in the system previously had been in due relation to the frame, and to the capacity and state of the vascular system. It frequently is observed in practice, that a previously healthy person, in respect of his vascular system especially, is exposed to causes which arrest the cutaneous excretions, and he experiences a slight attack of fever, or local determination to some predisposed organ, or diarrhœa, or some other affection, especially if the kidneys have not performed a vicarious office in supplying the suppressed function of the skin. A healthy person, also, is exposed to causes, as infections, which depress organic nervous energy, and thereby impair or suppress the more important depurating and secreting functions. The consequences as respects the blood are obvious. This fluid soon abounds in effete and injurious elements, increasing both the amount of vascular contents, and oppressing and irritating the whole vascular system, although certain organs may manifest these effects in a more prominent manner than others, until a salutary crisis is observed, and the morbid state of the blood is removed; or until the soft solids are changed, their vital cohesion is loosened, and disorganisation ensues.

103. *G.* I need not pursue this subject further, seeing that I have fully discussed it in several parts of this work; but I wish to direct attention to one topic more particularly connected with it, and

which, in its relations to various maladies, has been most unaccountably overlooked — namely, to the probable want of correspondence, on some occasions, between the capacity of the vascular system and the amount of its contents, between the area of the containing vessels and the amount of fluids contained. — *a.* This presumed want of adaptation, or of accordance, may be great, quite irrespective of the quality or condition of the circulating fluid; the tone of the containing vessels being so remarkably deficient, owing to depression of the organic nervous power, as not to occasion the due accommodation between the vessels and the blood circulating in them — as not to admit of that amount of vital contraction and adaptation of the vessels necessary to the due performance of the circulation, and to the retention in them of the more fluid parts of the blood, which, either alone or with more or less of the hæmato-globulin, readily escape from the relaxed capillaries in the more yielding surfaces and erectile tissues. Now, a due correspondence between the containing vessels and the contained fluids, and the mutual influences both vital and mechanical resulting from this correspondence, and from the healthy conditions of both the vessels and the fluids, are obviously wanting, in a more or less remarkable manner, in many maladies, especially in several malignant and pestilential fevers, more especially where the vital powers are remarkably depressed; and it is chiefly owing to this depression that the vascular system is incapable of accommodating itself to the amount of its contents. In these circumstances the pulse is at first broad, open, soft, and compressible, although it is subsequently small, feeble, creeping, or undulating; and the abstracting of even a small quantity of blood, or the loss of it by the passive hæmorrhages or exudations, which often occur very rapidly, sinks the patient, by increasing the want of correspondence, now pointed out, between the capacity of the vessels and the amount of blood they contain.

104. *b.* This want of correspondence, or of vital accordance, between the bloodvessels and their contents, may arise also from a different pathological condition, namely, from the blood being so deficient in quantity, as not to impart the requisite state of *tension* to the coats of the vessels: and hence, when the vital tone of the vessels is impaired at the same time that the blood is deficient in quantity, the current of the circulation is irregular and languid; and vascular action, which was already asthenic when the vital tone of the vessels was impaired, becomes much more asthenic when the blood is also deficient in quantity, fatal congestion and sinking of the vital powers ultimately supervening.

105. In pestilential maladies, and even in other malignant diseases, the tendency to death is to be imputed as much to this increasing want of accordance, — to the progressive defect of vital and mechanical adaptation, between the vessels and the blood, as to the changes which have actually taken place in the constitution of the blood; and several of the associated phenomena, characterising the advanced and last stages of these maladies, are to be ascribed to this circumstance, — to this pathological condition existing so generally throughout the vascular system. Thus, in the hæmagastric pestilence, or true yellow fever, the phenomena observed in its progress, and the acceleration of death by passive hæmorrhages, or the black vomit, in its last stage, are readily explained according to this view; whilst the more successful mode of treatment for this malady is that which is directed to these changes in the vascular system, and to the state of organic nervous influence upon which these changes originally depend.

106. That this want of accordance between the amount of blood in the vessels and the capacity of the bloodvessels, this deficient vital adaptation of the vessels to the amount of their contents, is a most important pathological condition existing in the progress of several malignant diseases, and associating the affections of distant organs; and, moreover, that death in these diseases is to be imputed rather to this circumstance, to this condition, than to the poisoned or altered constitution of the blood, heightened as it often is, at an advanced stage, by passive hæmorrhages, are facts illustrated by the course of several maladies, and demonstrated by what is observed after death from hæmorrhages and from hæmagastric pestilence. In the last stage of this latter malady, and as the altered blood — altered as regards its vital condition, physical appearances, chemical condition, and in the loss of the greater part of its fibrin — exudes from the mucous surfaces and outlets, the circulation becomes remarkably slow, the vessels appear and feel soft, relaxed, flaccid, and imperfectly filled; the blood returns to the right side of the heart in deficient quantity and celerity; absorption of fluid from the digestive organs is arrested; and ultimately the heart's action ceases, from an insufficient return or supply of blood to the right auricle. Upon examination after death, the digestive canal contains much black grumous matter, consisting chiefly of altered blood, or of matters similar to those thrown off from the stomach and bowels for some time before death; the abdominal vessels, and especially those contributing to the portal system, the ramifications of the vena porta, and the hepatic veins, are empty, and the liver is remarkably pale. The whole vascular system is deficient of blood. Analogous changes characterise the last stage of other maladies, as pestilential cholera, plague, &c., the chief difference being, that, in the former especially, the watery parts of the blood are those principally lost, the parts which are left being not only insufficient for the maintenance of a due correspondence between it and the vessels, but also unsuited to capillary circulation, and to the sustentation of the vital functions; the soft solids being also more or less deficient in vital cohesion, and rapidly passing into dissolution, as I have shown on several occasions, and especially when treating of these maladies.

107. *H.* It being admitted, and the fact cannot be disputed, that changes in the quantity and quality or state of the blood, and, still more remarkably, changes in both quantity and quality, associate disease of several organs, both those intimately connected anatomically, and those more distantly related physiologically, it must necessarily follow that not merely functional disturbance of these several remote as well as proximate organs is thereby produced and associated, but also structural changes and the most extensive disorganisations of these organs often result. But it is

not sufficient for us to take for granted these changes in the blood and vascular system, in thus complicating or associating disorders and distempers, and in developing various sympathetic ailments: it is of importance to us to trace these changes to their sources, and to view their relations, in order that we may the more fully comprehend their extent, and hence be enabled the more satisfactorily to prevent their accession, to arrest their progress, or to counteract their effects. I have already pointed out, briefly and inadequately, several of these sources and their pathological relations, and referred to the parts of this work where these topics are more fully discussed, and therefore I shall now merely enumerate the several conditions to which attention should be directed in our investigations of the sympathies or the morbid associations and complications resulting from alterations of the blood and vascular system.

108. *Firstly*, the state of organic nervous influence in relation to the agents affecting it, and to the resulting influences and changes upon the vascular system and blood.

109. *Secondly*, imperfect chymification and chylification, owing to the unwholesome nature of the ingesta, or to impaired digestive function, or to morbid states of the digestive mucous surface; the chyle being either imperfectly elaborated, or of so unhealthy a constitution, as to affect the glands and viscera through which it circulates whilst passing onwards to the blood, and after it has mixed with this fluid.

110. *Thirdly*. The absorption of morbid secretions, excretions, or other matters, either from the digestive canal and mucous surfaces, or from cellular parts, or parenchymatous organs or other structures, these matters often inflaming the blood-vessels or the absorbents and glands, contaminating the blood, producing chronic or hectic fever, irritating or inflaming remote vessels and organs, or giving rise to abscesses or purulent deposits, diffused or encysted, primary or secondary, in distant parts, as more fully shown in the articles "*Abscess,*" "*Absorption,*" "*Blood,*" and "*Disease,*" in this work, and in my paper on the "*Pathology of the Veins,*" in the Medical Gazette.

111. *Fourthly*. Suppression, interruption, or diminution of any of the eliminating or depurating functions — of either of the excretory actions, by which effete materials are removed from the blood, and this fluid is preserved in a healthy condition; interruption of one or more of these functions, altering the state of the blood, changing the healthy relations subsisting between it and the heart and vascular system generally, disordering the other excreting organs, exciting general vascular disturbance, and superinducing various changes, contaminations, effusions, and even disorganisations in several organs or parts, or generally throughout the frame.

112. *Fifthly*. The exciting, or depressing emotions of mind,—all influences, excitants, or agents, affecting either the cerebral, or spinal, or the ganglial sensibility — all inordinate excitations of the mind, passions, or sentiments; or of the senses and muscular movements; or of any of the organs requisite to the continuance of the life of the individual, or the perpetuation of the species, are liable to be followed by sympathetic disorder of distant but related parts, owing to the organic nervous connections already pointed out, to the changes frequently produced in the fluids — the chylous, lymphatic, and sanguineous — to the consecutive changes of nervous power, and electro-motive conditions of the general systems of the body, and to the *unity*, as well as to the special systems and conditions, of the frame.

113. From one or other, or from two or more, of these, numerous associated morbid conditions result, some of which conditions have been variously estimated and classed, with the narrow but vain view of giving them the individuality and identity displayed by the genera and species of the animal and vegetable kingdoms, characteristics which they are altogether incapable of evincing, owing to the diversified features, associations, and complications resulting from these five great sources, and their innumerable states, modifications, and progressive changes. The most common, at the same time the most uniform of the special results, proceeding from these sources, the most frequent of these sympathetic associations and morbid complications, in which changes throughout the whole frame are most remarkably produced, and most intimately dependent upon each other, through the *media* especially of the organic nervous system, and of the vascular system and blood, are the following:—

114. 1st. Sympathetic or symptomatic states of vascular excitement or action, resulting from changes in the organic or cerebro-spinal sensibility of parts; or from local injury, or from inflammation, pressure, or other local changes,—*symptomatic fevers.* The media of general disorder in these are, firstly, the nervous systems, and consecutively the vascular system and blood, the several concomitant and intercurrent changes, varying in different cases with the nature of the causes, and the numerous circumstances connected with these causes, and with the individual affected.

115. 2ndly. Chronic or hectic febrile conditions, resulting generally from a persistent source of irritation implicating primarily the organic nervous function, and consecutively changing the nutrition and secretions of the part, and ultimately altering the states of vascular action and of the blood; followed frequently by absorption of morbid or puriform or tubercular matters into the circulation, by consecutive deposits, abscesses, &c. *Hectic and chronic fevers,* consequent upon local irritations, tubercular deposits, encysted abscesses, carious bones, and malignant formations, &c., are all of this description, and are ultimately accompanied by altered conditions of the blood, imperfect assimilation, anæmia, &c.

116. 3rdly. Periodic fevers, or febrile and painful states of the system, arising from malaria, and varying in character with the concentration of the effluvium, and with the proportion or amount of emanation from dead animal matter which is conjoined with it. The morbid impression in these diseases is made primarily upon the organic nervous system, the vascular system and blood being consecutively affected, and various visceral affections often ultimately resulting.

117. 4thly. Adynamic, typhoid, and putrid fevers, or those arising from the emanations proceeding from living or dead animal matter. The morbid impression is made by those emanations primarily and principally upon the organic nervous system, although the blood may also be primarily con-

taminated, as it obviously is consecutively, the soft solids generally becoming, through these media, ultimately more or less implicated.

118. 5thly. Exanthematous and pestilential fevers, or those fevers arising from specific morbid poisons. The morbid impression is generally made in these distempers in ways similar to those now stated, §. 117., and the results are equally general and serious, often most rapidly fatal, particular fevers presenting peculiar characters.

119. In all these maladies, although the organic nervous system, in the usual mode of exposure to these exciting causes, receives the first morbid impression, especially when the poison is inhaled with the air into the lungs, the blood soon becomes contaminated, owing either to the absorption of a portion of that poison, or to the influence of the primarily induced morbid condition of the organic nervous system, in impairing the several secreting and excreting functions, and in altering in this way not merely the healthy constitution of the blood, but also the vital adaptation of the vascular system generally and of the amount of blood to each other; and, moreover, in destroying, both by the primary impression on the organic nervous system, and by the consecutive effects, the vital cohesion of the several simple tissues, structures, and compound organs.

120. These several classes of disease, whether viewed individually or in the aggregate, remarkably illustrate the great extent to which not merely functional disorder, but structural disease, and even more or less general disorganisation, may be associated, when a poisonous influence impresses any one portion of the congeries of ganglia and plexuses constituting the organic nervous system, or contaminates the circulating fluids; the effects being the more rapid, the more general, and the more fatal, the more concentrated or intense the poison, and the more unequivocally and immediately the primary changes are produced, both in this system and in the blood and vascular system.

121. The influences affecting the circulating fluids may therefore be classed under four heads: *first*, that of the nervous systems, more especially the organic nervous influence; *secondly*, the state of the chyle resulting from the nature of the ingesta; *thirdly*, the absorption of morbid or poisonous matters into the circulation, from any surface, organ, or part; *fourthly*, interrupted excretion.

122. Important and extensive changes are produced on the blood by the several eliminating organs, by the liver, the digestive mucous canal, the respiratory surface, especially the lungs, the skin, and the kidneys. An interruption to either or several of the functions of these organs, more or less alters the circulating fluids; but when the constitutional powers are not materially affected or depressed, a slight interruption to the discharge of one excreting function is very frequently followed by vicariously increased action of another excreting function, and thus the system is preserved without experiencing much detriment, in many cases of such interruption.

123. *I.* The importance of considering the state of the blood, with reference to the causes affecting it, is remarkably great, particularly with reference to fevers. In the different forms of fever, where disorders of function, and ultimately structural changes in the organs themselves, become the most extensive, it is seldom that we find one organ implicated alone, but several in rapid succession, or contemporaneously. Inflammatory lesion of a particular tissue or organ, with which the system sympathises through the channels pointed out, namely, nervous organic influence, the blood, continuity and contiguity of surface or structure, implicates the whole frame. The functions of the most remote organs become affected thereby, and generally, in proportion to the extent to which the circulating fluids are disordered. If vascular action, and especially if the circulating fluids be materially affected, coordinate disorder of the urinary and digestive organs, and also of the functions of the brain, generally ensues. Owing to the bonds which unite the frame into a whole, and intimately associate all the viscera, it has been supposed that all fevers are merely the general or sympathetic disturbance of this whole, arising from a more or less prominent affection of one organ. Several writers have attempted thus to localise all forms of fever; and to consider them merely as modifications of inflammatory fever; but I need not allude to these attempts, as they have been disproved when treating of the pathology of fever.

124. It would be interesting, if space allowed, to trace the manner in which the several systems of the frame become affected during the progress of fevers. In respect of periodic fevers, or those which arise from malaria, it may be briefly remarked, that the causes producing them seem to affect primarily and especially the organic nervous system; and that the fluids and abdominal viscera become more or less disordered secondarily. Intermittent and remittent fevers may not appear until weeks after the individual has been exposed to malaria, and then the paroxysms occur at intervals. We know that morbid impressions, or irritations, or other morbid conditions of nervous parts, usually assume a periodic character. If it were the blood which is primarily affected in these cases, it must follow that the state of the blood which existed during the paroxysm would continue during the intermission, until removed; and that, instead of presenting intervals when comparatively little disorder is felt, the disease would be continued; for, in proportion as the blood becomes affected in fever, so does the disease assume a more and more continued type. There are various lesions prominently affecting particular organs, and which give fevers a variety of character: thus we have gastric fever, intestinal fever, bilious fever, and so on. If we proceed to the consideration of the worst forms of fever,—for instance, typhus, or pestilential fever,—not only is the nervous system affected, the organic nervous system being probably the first to be impressed with the cause of the disease; but also the blood itself soon becomes more or less contaminated and altered — becomes physically changed.

125. Now the question is, whether this change, produced so early in the blood in typhoid and pestilential fevers, arises primarily from the absorption of the cause into the blood, or whether it proceeds from the morbid impression made primarily on the organic nervous system, owing to which impression the excreting or depurating functions, which are under the influence of this system, are impaired or arrested, and the circulating vessels and fluids become thereby affected,

and ultimately changed? I have shown how copiously the vascular system is supplied by the organic nervous or ganglial system, and hence we may expect, *à priori*, that causes affecting this system will, to a co-ordinate extent, affect the vascular system and the fluids circulating in the vessels. We find that, in the progress of fevers, the blood becomes changed; and the change may arise partly from the impression made by the emanations causing the fever upon the organic nervous system, and partly from the absorption of the emanation — of the morbid poison itself—into the circulating mass. I believe that the infecting or morbid effluvium being received into the lungs with the air, injuriously effects the organic nervous system supplying these organs; hence the blood in the lungs is not sufficiently changed by respiration. Possibly, also, partial absorption of this effluvium may take place into the blood itself; but if it does not, there is a still stronger reason to infer that the morbid impression extends throughout the organic nervous system, impairing or otherwise altering the influence of this system upon the vascular system, and in the secreting, assimilating, and excreting viscera. The organic nervous power being depressed, it naturally follows that the organs supplied by this system become impaired in function; and hence we find that, in the first days, or within the first twenty-four hours of fever, the functions of the excreting organs are very remarkably diminished, or even suppressed, and the consequence is, that the blood, which may have been hitherto unaffected, is more or less changed; or, if it have been already affected by the cause of the disease, or by the impression on the ganglial system, becomes still further changed. Thus the one change reacts on the other, and promotes it, until at last the changes in the organic or vital nervous influence, in the vascular system, and in the circulating fluids, become so great, that the blood is not only altered sensibly as respects both its physical characters and its chemical qualities, but the tissues and organs themselves become more and more disorganised, or evince a remarkable loss of their natural vital cohesion, especially in putro-adynamic fevers and in distempers of a malignant character. This subject is so fully illustrated in the articles BLOOD, DISEASE, INFECTION, FEVERS, and PESTILENCE, that it is unnecessary to pursue it further at this place.

126. ii. *The influence of obstructed circulation through, or of other lesions of, the heart itself, independently of any material change in the constitution of the blood in complicating diseases*, and the intimate connection existing between the circulation through the heart and that through the lungs, have been already adverted to; but so much have we been in the habit, in consequence of the modes of teaching and writing generally adopted, of viewing disease nosologically, and of regarding one species as being altogether distinct from another; and so injuriously has this acted in the practice of medicine, that we have been thereby actually prevented from seeing the connection subsisting between different diseases, and of observing how intimately they are associated, and how readily the disorder of one organ induces, or passes into, that of another, until experience and repeated observation have destroyed the impressions of erroneous education and of false precepts. We often observe persons with short or hurried respiration on the least exertion, which has often been considered as a form of asthma, and the disease has been looked for in the respiratory organs. The patient has been said to have spasm of the bronchi or the trachea, or some disorder of the respiratory passages, which has produced this disordered respiration. But now that we have traced out more intimately the relation of the disorder of one organ to another, we have found that in these cases the lungs may be free from disease, further than congestion arising from interruption to the circulation through the heart; and we have discovered that, in the majority of such cases, the lungs are only secondarily effected, and that the heart is primarily in fault. This condition of the respiration is most frequently owing to this cause, even where there is but slight disease in the heart. Thus in weakened, nervous, and susceptible persons, the affection of either organ soon extends to the other. If the lungs are disordered, the heart becomes affected; or if the heart is primarily affected, the lungs become disordered — the least excitement of one organ extends to the other. In many persons of lax fibre, or of a lymphatic or leuco-phlegmatic constitution, the parietes of the heart are deficient in tone, or are partially changed in their intimate structure, and dilatation of the cavities, or other alterations, often take place, so as to give rise to imperfect or irregular or interrupted circulation and consequent congestion, with or without effusion, either in the vicinity of the congested viscera or in more distant parts; *the subordinate circulating apparatuses, or the subordinate orders of the vascular system, namely, the vascular apparatuses of the liver, brain, and lungs, especially suffering derangement.* Numerous instances present themselves in practice of consecutive affections, of a complicated character, appearing as the disease advances, during hooping-cough, dry catarrh, asthma, &c.; the heart, the brain and spinal cord, and their membranes, the portal circulation, &c., becoming secondarily affected, in addition to organic changes, often also produced in the lungs themselves, and in their investing membranes.

127. The connection subsisting between dilatations, often slight, of one or more of the cavites of the heart, and betwen lesions of the valves and orifices, and congestions of the subordinate orders of the vascular system just specified, more especially those of the lungs, liver and brain, is sufficiently obvious, particularly when the heart betrays any of these lesions. But there is every reason to infer that congestions of the lungs may actually take place to even a fatal extent, without any very obvious organic lesion of the heart, or lesion of such an extent as can account for the occurrence. Thus severe shocks to the nervous system, mental or physical, severe injuries of vital parts, and agents acting with great intensity, and either inordinately depressing or exhausting vital power, occasion remarkable congestion of the lungs, sometimes also of the other subordinate orders of the vascular system, more especially in persons already the subjects of a fatty, dilated, or relaxed state of the parietes of the heart's cavities. Congestion of the lungs, however induced, even in slighter grades, is a serious morbid condition, inasmuch as it arises

from, or is connected with, various other lesions, either of vital action or of structural change, especially of the parts now stated; and as it generally leads on to further alterations, to inflammatory action, to hæmorrhages, and various organic lesions, especially when neglected or improperly treated.

128. iii. *The sympathies between states of the circulation and those of the digestive organs* are so obvious as hardly to deserve notice. The functions of digestion and assimilation languish when those of circulation and respiration are impaired; and when the respiratory, and especially the circulating actions, are morbidly excited, distaste of food, nausea, thirst, and costiveness are common consequences. In these circumstances the digestive villous surfaces become injected or congested, and the vascular disorder is often imputed to, instead of being viewed as causing, this change. Wherefore, it may be asked, are these surfaces often so prominently affected in cases of general vascular excitement? Because the vascular excitement does not always extend to the portal circulation, and the return of blood from the related viscera through the portal and hepatic veins is not so rapid and complete as the circulation through the arteries supplying the digestive canal; hence the congestion in many acute and chronic diseases of the digestive villous surface, and the rapid disorganisation often consequent upon it, especially when organic nervous power is depressed, as in malignant or pestilential fevers, in gastric remittents, and in typhoid, adynamic, and intestinal fevers.

129. The liver also often experiences consequent congestion or other disorder when the general circulation is either much accelerated, as above, or much impeded, as in cases of cardiac or pulmonary disease. The frequent occurrence of congestion of the liver in the course of these and other maladies, especially of those affecting the organic nervous influence, is a matter deserving notice. This congestion may be, in a great measure, owing to the circumstance of the circulation through the portal vessels being almost entirely removed from the influence of the heart. The circulation through these vessels appears to be owing to the organic nerves which supply them, and when the influence of these nerves is depressed, the circulation in the liver is co-ordinately impaired or impeded. I believe also that the capsule of Glisson is also very influential in promoting this circulation, and this capsule is abundantly supplied with soft ganglial nerves, whereby the vital action of the portal vessels is reinforced with nervous influence. In all cases where there is cardiac disease, and congestion of the lungs consequent upon it, there is generally congestion of the liver. Both organs are intimately associated by means not only of the vascular system and the circulating fluids, but also of organic nervous influence, both organs being supplied by the same class of nerves. Again, the circulation through the liver, to which I have already partially adverted, is very much influenced by the state of the fluids and matters absorbed into the circulation even from the stomach itself, but principally from the intestinal canal. Stimulating, irritating, or imperfectly assimilated matters, when carried into the portal circulation, must necessarily irritate or excite the liver, and thereby ultimately produce changes of its structure.

130. iv. *The sympathy existing between the cardiac and pulmonary circulation and the brain* need only be mentioned to be admitted. The effect of disordered circulation through the heart upon the brain is a matter of very great importance, and one which, until recently, has not been sufficiently adverted to. The subject, however, has been fully discussed in the articles on Apoplexy and Diseases of the Heart, where it was shown, that a number of cases of congestive apoplexy, of hæmorrhagic apoplexy, and of palsy, are occasioned by interruption to the return of blood from the head, owing to lesions of the parietes of the heart's cavities, or of the valves and orifices of the heart, with or without congestion of the lungs, according to the side of the heart in which the primary lesions are seated. This is a complication of very great importance, inasmuch as the symptoms are usually referred to disease of the brain, and are often considered premonitory of apoplexy or palsy, and are often treated as such without reference to the state of the heart, the pulse being tolerably regular; and yet, on examining the heart by auscultation, serious disease of this organ is found. I have had many patients who have long complained of symptoms referable entirely to the brain, the heart betraying to them not the least disorder, and yet in this latter organ was seated the primary, and often the most extensive disease.

131. Owing to insufficiency of the valve, or to dilatation of the right aurico-ventricular orifice, or to what is a still more rare occurrence, to disease of the valves at the commencement of the pulmonary artery, occasioning obstructed circulation, there is regurgitation of blood from the ventricle into the auricle, and then a series of changes supervene, as respects the circulation not only in the brain, but also in the liver and kidneys. At first, lesion of the functions of these organs, or of one of them in a more prominent manner, is observed, with more or less remarkable congestion; and subsequently structural change, with either serous or sanguineous effusion, anasarca, hæmorrhages, &c. The blood being partly thrown back at each contraction of the ventricle into the auricle, the regurgitation into the vena cavá superior and inferior occasions congestion of the brain, liver, and kidneys, and its consequences, as just assigned. When there is dilatation of the right auriculo-ventricular orifice, or insufficiency of the valve, the effect upon the venous circulation is made manifest in the pulsation of the jugular veins, and the consecutive lesions just mentioned soon supervene. I have observed these associated changes in the cases of three eminent medical men who were under my care, and in two of whom I had an opportunity of making a post-mortem examination.

132. When these lesions occur in the left side of the heart, and which situation is much the most frequent, they interrupt the circulation through the lungs: congestion of the lungs takes place, and, in consequence of it, I have seen the changes supervene that I have now mentioned with reference to the right side of the heart. The congestion is usually to a great extent, and there is either effusion into the pleural cavities, or hæmorrhage of the lungs, or pulmonary apoplexy. There are other associated changes which require merely to be mentioned, but I shall allude only to organic diseases of the heart and kidneys. When treating

in the article Kidney, on granular degenerations of this organ, I fully showed that they were the results of a cachectic inflammation of the secreting structure of the kidney, especially of the Malpighian tufts, consequent upon a morbid state of the blood, and were sometimes also connected with organic changes in the heart and other viscera.*

133. In briefly adverting to *the association of disorder of the circulating, nervous, and muscular systems*, I need only remark that, when the chyle or blood is disordered, these other systems are all more or less affected—the muscular system chiefly, through the medium of the nervous. Irritation of lymphatic or lacteal vessels, either at their origins, or by the fluids which they imbibe and transmit, affects the glands through which they pass, or in which they terminate. When the lacteals are irritated, especially at their origins in the small intestines, the irritation is often propagated to the mesenteric glands, or to the portal veins and liver. Indeed, the digestive mucous membrane is seldom affected, especially in children, without causing disease of the mesenteric glands, particularly if the malady goes on to ulceration. It has been believed that, not only under these latter circumstances, but also in chronic dysentery, more especially as it occurs in warm climates, the consecutive abscess of the liver, frequently met with, is not merely owing to the absorption of morbid matters, purulent or acrid, from the digestive mucous canal, which irritate or inflame the liver or its vessels, but is actually the result of a true phlebitis, commencing in the veins of the mucous surface, and propagated along the veins contributing to the portal system, and thence to the ramifications of the vena portæ. In disordered states of the blood, when this fluid becomes vitiated, not only the muscular system, but the joints are also often affected. I have already hinted at this connection, as arising from the circumstance of the ganglial nerves not merely supplying the blood-vessels of the extremities, but also being distributed to the joints, in the vicinity of which they form minute ganglia; and hence, when the organic nervous system is much depressed or weakened, there is always great weakness of the joints. In this way may various phenomena that occur in many diseases be explained. Thus, gout and rheumatism arise not merely from the morbid condition of the blood, but also from the state of the organic or ganglial nerves supplying those parts, and from the connection of these nerves with the cerebro-spinal sensory nerves.

134. V. Sympathies of Sensation and Sensibility, or Associated States of Morbid Sensation and Sensibility.—After my endeavours to point out the intimate association of the ganglial with the spinal nerves and nerves of sense, it will be unnecessary to revert to the channel of communication in the associated affection of this class. It is only requisite to notice certain of these associations. Owing to the intimate connection of the fifth pair of nerves with the nerves of sense—with the optic, lingual, auditory, and olfactory—a change affecting the roots or trunk, or even the ramifications of the fifth pair of nerves, to a certain extent impairs one or more of the senses on that side on which this nerve may be affected or implicated. Thus, in cases of tumor or abscess pressing upon the gangliated portion of the fifth pair of nerves, not only is the sensibility of the surface affected, but also the circulation and secretions of the organs of sense on that side are either disordered or impaired. Inflammation of the conjunctiva readily supervenes, and the senses of smell and taste are affected partly in consequence of diminished secretion from the surfaces of their respective organs. All the functions of sense are more or less affected, not only by disease implicating associated nerves, or parts from which the nerves take their origin, but often also by disease in distant situations. Even depressed

---

* The article Kidney was published in 1840, and since the publication of that article views entirely identical with those which I then stated and illustrated have been brought forward by some very recent writers, as previously unpromulgated by any other. I think it therefore due to myself to state, and to refer to the parts and the *sections* of this work, and to the *dates* where my statements as to the topics connected with albuminous urine and granular disease of the kidney, or *Cachectic Nephritis*, as I have termed this disease, may be referred to; the granular degeneration being the advanced stage of the cachectic inflammation. In 1832, I stated, when describing the states of the urine in connection with dropsies, that "renal disease may exist without the urine being albuminous; and the urine may be albuminous without the kidneys being particularly implicated." Also, that I have often found the urine albuminous in the acute diseases of children, where no alteration of the kidneys existed; and that this condition of the urine is frequently observed after the exanthemata. (*See Art.* Dropsy, §§ 34—36.)

When treating of the Diseases of the Kidney, in 1840, I entered very fully on the consideration of the pathology of the changes, which, when advanced, have been called "granular degeneration" of this organ; and showed that these changes, and consequently this degeneration, depend upon, or are intimately connected with, a morbid state of the blood; that, therefore, this particular disease of the kidney should be called, "*Cachectic Nephritis, Nephritis Cachectica; or Nephritis Sociata, associated or complicated Nephritis; or Nephritis from constitutional vice; or Nephritis from a morbid state of the blood, or Inflammation of the Malpighian bodies or tufts*," rather then the appellations conferred on it. (*See the Synonymes adduced under this head.*) And conformably with this doctrine I have defined the disease, *pathologically*, as follows:—"*A morbid state of the blood, characterised chiefly by the presence of urea and deficiency of albumen and of hematosine, in connection with lesion of the circulation in the minute glandular or Malpighian bodies and structure of the kidneys, with various organic changes in other viscera, and generally with serous effusion into the cellular tissue and shut cavities.*" (*See Art.* Kidneys, § 81.)

I afterwards proceeded to investigate and to describe various topics connected with the pathology, complications, and treatment of this malady, especially the particular tissue of the kidneys primarily affected; the connection subsisting between this disease and morbid states of the blood; and between it and other visceral maladies, and the origin of the changes of the blood, on which this disease of the kidneys is consequent (*see* § 82). I next described the physical appearances and states, and the chemical changes, of the blood in the several stages of the acute and chronic forms of this disease (§§ 93—97.); and afterwards noticed the sources and causes of this state of the blood (§§ 140, 141.). I would most particularly refer to *par.* 142. of that article, where the reader will find this topic explained, and the reason of both kidneys being always affected in Cachectic Nephritis.

Now Dr. Finger, of Prague, Dr. Walshe, and Dr. George Johnson, have, long after the publication of the article on the diseases of the kidneys, adopted my views as to this malady, without any reference to them whatever; Dr. Finger stating that "the blood is first diseased;" and Dr. Walshe (*Lancet*, July, 1849) that the lesions of the kidneys are the consequences of previous alterations of the blood. Still more recently, Dr. George Johnson, in his Gulstonian lectures (*see Medical Times and Gazette* for March and April, 1852), has adduced the same doctrine of the origin of this disease; and I am therefore entitled to conclude, that the adoption of my views, and of the results of my investigations, by these very able pathologists, is a strong confirmation of their general accuracy. The several associations and complications of this malady, in connection with the progressive changes of the blood and of the kidneys, were more fully described in that part of this work than they had previously been.

energy of the organic nervous system generally, and especially of those parts of it which preside over digestion and assimilation, impairs the functions of sense. This association of remote organs — this unity of the frame — is displayed not only by one class of functions, but by all the manifestations of life in the different organs constituting the individual living being. I need not advert to the association of morbid sensibility of different parts of the cerebro-spinal nervous system. We are all aware that, when irritation exists at the origins of nerves, it is not there that we may expect to find sensibility principally affected. When the irritation even is greatest at the roots of the nerves, little or no pain or alteration of sensibility may exist there: it will be felt chiefly at the sentient extremities of those nerves. This is manifested by *tic doloureux*, in which the morbid condition exists near the base of the brain, or is connected with the duramater, or is caused by exostosis of some portion of the bones of the cranium. There may be pressure, or irritation caused by ossific deposits, but the morbid change is evinced principally at the remote or distal extremities of the nerves.

135. The same circumstance obtains with regard to the spine. In cases where the individual may not suffer the least uneasiness in the seat of pressure, or in any part of the spine, yet there may be extreme pain in the surface of some part supplied by nerves from that portion of the spinal cord which is implicated in the existing irritation or other change. Although the patient may not feel pain in the part especially affected, yet he may be suffering under inflammatory irritation, or congestion, or other organic changes implicating the spinal cord and membranes or the roots of the nerves. The suffering experienced in the extremities in gouty persons is not always owing to the changes in the extremities only, but partly also to congestion of the venous sinuses of the spine; and the partial palsy of the extremities, especially the lower, generally passing on to complete palsy, arises often from congestion of these sinuses, followed by effusion, or other organic changes. These are facts which I have had occasion to verify in several instances by inspection after death. When the change implicating the cord, its membranes, or origins of the nerves, is such as irritate, excite or similarly affect these parts, pain is usually manifested in the extremities of the corresponding nerves, and sometimes also by other nerves more or less intimately connected with them; but when the primary change goes on to the production of pressure, or to the destruction of parts, then loss of function, impaired sensibility, or difficult or impaired motion, or a combination of these, supervenes, and increases with the augmenting organic change.

136. Not only may irritation or pressure at or near the origins or roots of the nerves of sense and of motion affect the senses, the sensibility, and the motions, even to the remotest parts, but irritation, originating in or affecting the ganglial nerves, will produce serious disorder not only in the seat of irritation, but also in most distant places, which places often evince the chief disturbance, either in respect of their sensibility or their movements, or both. These occurrences are not infrequently verified by post-mortem examinations, the existing lesion being sometimes found in parts which evinced but little or no disorder during life, the severity of the sympathetic affection having attracted the entire attention of both patient and physician. The irritation produced by a calculus in the kidney, by sabulous matter in the tubuli of the organ, often produces disturbance of the organs supplied with nerves from the ganglion and organic nervous plexuses of the organ, extending even to the associated ganglia, and affects not only the urinary functions generally, but also the digestive, occasioning nausea, vomiting, constipation, colicky pains, &c.; and the extent of disorder is sometimes even not so limited, but still further extended. By means of the branches or fibrils of ganglial nerves proceeding from the renal ganglion to the roots of the spinal nerves, and even to the cord itself, as well as by means of spinal nerves proceeding to the sympathetic nerves and ganglia, a sympathetic affection — one consisting chiefly of pain, or morbid sensibility of a painful kind — is sometimes also experienced in various parts of the external surface, or in the course of a nerve, as it ascends to the shoulder or arm of that side, or more frequently down the lower extremity; occasionally with a peculiar numbness or imperfection of the voluntary movements. I have had opportunities of observing such cases, in some of which the pain was as severe as in neuralgia, where also the cause was suspected during life, and no appropriate treatment had previously been adopted. In two instances of recent occurrence, an examination was made after death, and large calculi were found in the kidney. Irritations of the ovaria or uterus, as will be noticed hereafter, develope even a still wider range of sympathies.

137. VI. Sympathetic Disorders of Animal Motion.—These are of great importance, and present the same relations as have now been pointed out; but I can only imperfectly advert to them at this place. Many disorders, even several that are seated in the abdominal cavity, may affect the locomotive functions; of this we observe daily proofs. Fæcal accumulations, or morbid matters, or worms, in the intestinal canal, often irritate the ganglial nerves, and the irritation is propagated to the roots of the spinal nerves, or even to the spinal cord itself, and is thence reflected by these nerves to the voluntary muscles, to the extremities, or to the external surface. In this way, chorea, infantile convulsions, and various symptomatic disorders, often of an anomalous character, implicating the muscles of voluntary motion, alterations of sensibility on the surface and in the extremities, various affections of the organs of sense, and many of the phenomena observed in cases of intestinal and gastric disease, are frequently developed. (See Arts. Chorea, Convulsions, Epilepsy, &c.)

138. There are numerous sympathies or associated morbid states indicated in the *synopsis* or *classification* (§ 14.) of the topics comprised in the very extensive subject here attempted to be discussed, but I must content myself with the mere indication of them thus afforded. The pathologist will readily recognise the importance of most of them, and the medical practitioner will readily furnish illustrations of them from his own experience. One of the chief objects I have in view is, to point out the principal channels of sympathy, or the media by which disorders become associated or complicated; the channels or media having been

recognised, the resulting phenomena, as actually occurring in practice, may more readily be referred to their sources, although they are too various and numerous to be adduced and illustrated in the space to which I am limited. Passing over, therefore, some of the subordinate orders of sympathies which may be ranked under the preceding classes, I shall conclude with a brief consideration of a class of sympathies to which sufficient importance has not always been attached, and which, indeed, has not always been rightly interpreted or understood.

139. VII. The Sympathies evolved by the Reproductive Organs appear about the period of approaching or fully-developed puberty. The influence of the sexual organs upon the economy is evinced at this period by the more rapid growth of the whole body, and by the more complete development of all the structures and organs, and of all the manifestations of mind: and this evolution of the physical and mental constitution of the individual is the more perfect and complete when, circumstances being favourable in all other respects, these organs have not been prematurely excited, exhausted, or abused; for accurate observation will confirm the position, that abuse, or premature excitement of these organs, or excess of such excitement, diminishes or weakens the growth of the body, or impairs the energy of both the organic and the cerebro-spinal nervous systems; and, with other injurious effects, often carried to an alarming extent, impairs or even altogether destroys the chief manifestations of mind, and developes several constitutional maladies and numerous special diseases, with their still more numerous sympathetic associations. The evil is not limited to the delinquent alone, but extends to the offspring of him or her who has indulged in the vices to which reference is now especially directed —if, indeed, such creatures be capable of reproducing their species. If this power be still retained, it is generally manifested weakly, imperfectly and insufficiently, as regards the constitution, physical and moral, of the offspring.

140. Whilst the perfection of mental and bodily function, as well as of corporeal development, thus results from the full evolution of the sexual organs, or from the reciprocal influence exerted between them and the nervous systems, numerous disorders, evincing more or less extensive sympathies and associations, are produced by the causes now alluded to — by abuses of these organs. The exhaustion thereby caused affects not one organ merely, but the whole frame. This generally extended sympathy — this universally diffused state of disorder — is to be explained partly by the exhaustion consequent upon inordinate excitement, and partly by the excessive secretion and excretion of a recrementitious fluid — of a secretion intended not merely for the perpetuation of the species, but also for the support and development of the structures, and of the nervous power of the individual. This functional abuse extends its consequences thus generally, through the medium of both the organic and the cerebro-spinal nervous systems, impairing digestion, vital action and tone, sensation, perception, memory, volition, muscular motion, &c., and hence all these functions not merely languish, but also betray, in varying forms and associations, numerous sympathetic disorders, increased susceptibility of impressions, morbidly increased irritability, &c., whilst nervous power, and endurance, and vital resistance are diminished. Impaired assimilation and nutrition, and a general cachexia, are also among the usual results, even when no particular or specific form of disease is developed. Ultimately the organs, thus prematurely or inordinately excited, either have their functions entirely exhausted or assume an increased susceptibility of irritation, and become the seats either of very frequent or constant disorder, or of organic lesions, whence numerous sympathies irradiate. The morbid state of one of these organs partially extends to all: that of the ovaria affects the uterus and the mammæ, or that of the latter extends to the former. Irritation of either of these organs extends through the medium of the ganglial nervous system to the urinary organs, to the digestive canal, and to the secreting and excreting organs generally. Thus we perceive disorders supervene of the secretion or excretion of urine, flatulence, borborygmi, the globus hystericus, with other affections of the bowels and stomach, and even interruptions of the cutaneous, biliary, and intestinal secretions and excretions.

141. These disorders are almost universally experienced in these circumstances, and as the irritation of the sexual organs increases either in duration or intensity, or as the causes which occasion the irritation are persisted in, the sympathetic disturbances advance still further and more generally by means of the nervous communications already described; and ultimately, in consequence of superinduced alterations of the vascular system and circulating fluids, they are manifested in numerous modes in distant parts of the economy. The individual who has thus devoted himself or herself — it may be said to the infernal gods — soon afterwards, and owing to the sympathy manifested by the ganglial system, complains of palpitations or irregularities of the heart's action, of shortness of breathing, and other signs of pulmonary or cardiac disease, of indigestion or morbid states of the appetite, and of various anomalous pains or alterations of sensibility in different parts of the body. Owing to the connexions subsisting between the organic nervous system, the spinal nerves and cord, and the brain and nerves of sense, and owing to the association of the ganglial and spinal nerves in the organization of the reproductive organs, disorder in various forms is extended to, or is manifested by, the organs of sense, and the muscular and tendinous structures. Volition is often languidly or imperfectly transmitted by the voluntary nerves; the muscles become more and more unable to execute the weak or inadequate volitions; the fibrous and tendinous structures evince impaired vital tone, whilst sensibility and irritability present various aberrations. In conjunction often with these, or more or less independently of some of them, various congestions in different places, either in succession or coetaneously, or irregular distributions or determinations of blood, take place, and either heighten preceding ailments or develope novel forms or combinations of disorder. Congestions of the venous sinuses of the spinal column frequently occur, and disorder the urinary functions or affect the sensibility or movements of the extremities, producing partial, or even complete palsy, either of sensation or of motion, most frequently of the latter. The irritation existing in the primary seat

of disorder is often propagated to the roots of the spinal nerves or to the cord itself, and is thence reflected upon the surface of the body, or in the extremities, in the form of neuralgia, or in other states of altered sensibility, or in various forms of hysterical spasm, convulsion, or disorders of motion. The senses, especially sight, hearing, and touch, are variously obscured or modified, and the mind becomes more or less disordered. The individual whose organic and mental energies have become weakened by the causes alluded to, is envious of those who possess powers which he either never had or has lost; is censorious; indulges in scandal or in the depreciation of others; is mean, spiteful, or sanctimonious; or he becomes the subject of some variety of partial or even of general insanity, or of idiotcy and general palsy.

142. The most dangerous and advanced maladies resulting from the morbid condition referred to — the most serious and complicated mischief thus produced—varies with the constitution, predisposition, and concurring causes and circumstances affecting the individual. In many, asthmatic or pulmonary affections, tubercular consumption, and tubercular formations in different organs; in others, various forms of insanity; in some, organic disease of the heart; and in some, structural change in the brain or its membranes, occasioning epilepsy, palsy, &c., are the more remote consequences. Indeed, almost every form of special disease, with their numerous sympathetic associations, may be simulated, and actually produced, especially when aided by concurring causes, when irritation of the reproductive organs is either frequently repeated or inordinately perpetrated. At first numerous functional disorders are developed, which are continually changing their aspects and their associations, and varying in severity and character. Subsequently, and as these are neglected, or as the cause is continued, or as the original morbid condition increases, disorders which were formerly functional become ultimately organic or structural, chiefly in consequence of the influence which disordered states of organic or cerebro-spinal nervous influence exert upon the vascular actions, upon the assimilating and nutrient functions, and upon the several secreting and excreting organs.

143. Having thus attempted to direct attention to the sympathetic relations of disease, and to the channels through which diseases become associated or complicated,—my limits, however, obliging me to leave many topics connected with the subject altogether untouched,—I wish to impress upon the reader the advantages to be derived in practice, from tracing, as accurately as possible, the bonds of connection which associate or complicate the more specific and primary states of disease, and render morbid phenomena often difficult of interpretation, and as often difficult of removal. Having ascertained as accurately as possible the primary source of disorder; having traced the succession as well as relations of morbid manifestations, and the connection of the whole with antecedent and existing causes; having, moreover considered the probable extent of nervous disorder and of vascular disease, and of alteration or contamination of the circulating fluids, a rational basis is thereby formed for therapeutical indications and remedial measures; and, as respects both the general intentions and the particular means, these will be the more appropriately and successfully adopted.

144. I believe that the physician who thus enters on the study of each case which comes before him, and endeavours to connect the effects presented to his view with their causes, and to trace the bonds of union subsisting between those frequently distant effects, will generally exercise his profession successfully and honourably; for being acquainted, as he should undoubtedly be, with the nature and operation of the remedies he employs, he will apply them appropriately to the removal of those morbid conditions which he rationally infers to be present. A physician whose mind is thus tutored and practically engaged will be neither sceptical of the effects of medicine on the one hand, nor empirical and rash in the use of it on the other. This extensive and practical knowledge, being always appropriately applied, will prevent him from lapsing into a scepticism which, entertained by any member of our profession, is not degrading to the profession itself — for truth and honour cannot be degraded — but which is most degrading to the sceptic himself, inasmuch as he admits himself to be deluding the public, whilst he boasts that he is not himself deluded, and thus vaunts his own dishonesty. Neither will the enlightened and rational physician lapse into a state of blind empiricism, and wield the weapons employed against disease in such a manner as will not only endanger the life of the patient, but also injure his own reputation.

145. I have been anxious to entertain the subject now imperfectly discussed, because it has hitherto failed of obtaining an attention in any way commensurate with its importance. My limits have obliged me to omit several topics more or less intimately connected with it. The observations, therefore, which I have offered, will, I hope, be viewed as *suggestive* only, especially in respect of various subordinate topics, for as my space did not allow me to illustrate, I could suggest merely.

CLASSIF.: — GENERAL PATHOLOGY.

1. In the article DISEASE, I gave an ample sketch of the *Causation of Disease*, or *Ætiology*, not only mentioning the several occasions of disorder, but also arranging them and showing their modes of operation. I afterwards considered the *general doctrine of disease*, or PATHOGENY, and described the changes constituting disease, as they proceeded more immediately from the causes producing them; noticing in succession the simpler or dynamic changes, the more complicated or qualitative alterations, and the effects of these changes upon the secretions and excretions, upon the circulating fluids, and upon the nutrition of the several structures. After a sufficient consideration of the numerous topics comprised under these heads, I noticed the *Procession and duration of morbid phenomena*, the *Types or forms of disease*; the *Terminations of disease*; the *Relations, successions and complications of disease*; the *Metastases or conversions of disease*; and, lastly, the *circumstances modifying the Form, complication, duration and terminations of disease.* I thus developed, under the article Disease, a *system of pathology*, which, in certain of its parts, is more fully illustrated in the several articles on special topics — on the *blood*, on the *structural lesions* of the several tissues and organs of the body, &c.; and which, when connected with others, and with the article now commenced, will furnish the reader with comprehensive views of morbid actions, will demonstrate the relations and connections of these actions, and will enable him to arrive at rational conclusions as to their natures, and as to the indications and the means most appropriate for their removal, for their alleviation, or for their control. Having discussed the numerous topics referred to, I have now to notice the *symptoms and signs*, by which the *forms and states of morbid action* are recognized and duly estimated, especially as respects the *seats*, the *natures* and the *results* of such actions.

2. A knowledge of disease comprises not only a recognition of existing symptoms and signs, but also a due estimation of the value, importance, and source of each, the comparison of one with the others, the relations subsisting between them, the connections between them and their antecedents and causes, and the results which may be expected from them, and their various combinations and groupings. In estimating the importance of symptoms, as showing the seats, the limitations, and issues of morbid action, they require due consideration both in the aggregate and individually, and not merely as regards the associations they present, but also as respects the absence of others, which are indicative of the seat, nature, extension or issue of other special diseases, or of distinct but allied or similar states of morbid action; — absent manifestations of disease should be taken into account in our estimation of the value or importance of those which are present.

3. *The Manifestations of disease*—the symptoms and signs by which the seats and natures of diseases are indicated — are, 1st., vital or spontaneous, or strictly sympathetic and symptomatic; or 2d., physical or artificial. The former of these only are comprised in this article, the latter have been fully discussed in the articles ABDOMEN, AUSCULTATION, CHEST, SUCCUSSION, &c. In treating of *the Sympathetic and Symptomatic Manifestations of disease*, or of *Symptoms* more especially, I shall *first* notice those which appertain to the *appearance* and *attitude of the body*, and to the *Animal, Loco-motive, and Sensory functions*; *secondly*, those which belong to the *Respiratory and Circulating Organs*; *thirdly*, those which are manifested by the *Digestive and Assimilating Organs*; and, *lastly*, those which concern the *Urinary and Sexual functions and organs.*

4. I. SYMPTOMS AND SIGNS APPERTAINING TO THE ATTITUDE AND APPEARANCE OF THE BODY, AND OF THE ANIMAL FUNCTIONS.—Numerous changes in the attitude and appearance of a patient at once strike the experienced observer, and suggest a general and often a correct idea of the nature of the disease which he is called upon to treat.—i. THE ATTITUDE AND GENERAL APPEARANCE OF THE BODY furnish signs both of the nature and of the tendency of the disease. A constantly retained position on the back indicates depression of vital power, and, in febrile diseases, extreme exhaustion or asthenia. It is most remarkable in low, typhoid, adynamic or pestilential fevers, and in the last stage of acute maladies, especially when, with extreme exhaustion of organic nervous power, there is either low or muttering delirium, or unconsciousness, or coma, or more or less contamination of the circulating fluids. When this position is long retained, especially without due attention to cleanliness or dryness of the surface, the more prominent parts or those most pressed upon, become inflamed, ulcerated or gangrenous; and the results are often fatal, unless the local and constitutional treatment be active and appropriate. If this position be attended by a sinking or falling down in bed, owing to a tendency of the body to gravitate to the lower or more depending parts of the bed, and to lost power of the extensor muscles, the positions of flexible parts being somewhat bent, and the head gravitating in the direction where the support is the least, the exhaustion of vital power and the consequent danger are the greatest, especially in the maladies just named. When the patient becomes capable of recovering his position when he feels himself falling down in his bed, or falling from his pillow, and especially when he is able to turn to either side, and to retain for a time a position on his side, or even partially on his side, it is one of the earliest indications of returning powers in low or adynamic febrile maladies. The supine position, with the knees drawn up, so as partially to relax the abdominal muscles, and to keep off the pressure of the bed-clothes, indicates morbid sensibility or inflammation, or both, of one or more viscera in the abdominal cavity, and more especially peritonitis, enteritis, gastritis, &c. In these cases, the supine position is retained, not so much in consequence of exhaustion, as in order to remove the pressure of the contiguous viscera from the diseased parts.

5. The sitting attitude, the inability to lie down in bed, the necessity of being shored up in bed, and various sitting positions, are important indications of the diseases to which the physician's investigations should be particularly directed. The sitting position can hardly be relinquished in dyspnœa, asthma, in organic diseases of the heart, in extensive effusion into the pleural cavities, in bronchitis of both lungs, in laryngitis, in many cases of congestive or asthenic pneumonia, and in severe or complicated cases of epidemic influenza. In the worst states of these especially, the patient is unable to repose on either side, without great increase of his sufferings, inasmuch as the weight of the upper regions of the trunk upon the side, on which he rests, greatly impairs the respiratory functions of that side, whilst the action of the side left free is insufficient for the respiratory changes, and for the purposes of the economy.—In less severe or urgent cases, the patient retains a semi-supine position, by having the shoulders and head elevated by pillows. In the more extreme cases of these maladies, the patient is obliged to lean forwards, and often to place his elbows or arms on the table in order to procure a fixed point for a stronger contraction of the muscles of respiration. In protracted cases of this kind, the shoulders acquire an unnatural elevation, and are directed upwards and to the ears.

6. A restless mode of lying down accompanies severe states of thoracic inflammation and acute rheumatism, and several organic maladies. A quiet position on lying down, with perfect consciousness and returning strength, indicates a favourable termination. This position, however, is retained in rheumatism in order to avoid the pain occasioned by moving. Lying on the abdomen, and tossing from the prone to the supine position, or from side to side, attend violent colicky pains, and ileus, or the passage of gall-stones, and hysteria. Patients often prefer to lie on the right side in health, and generally in pneumonia, in bronchitis, and in cases of pleuritic effusion, of this side, after pain, or the more acute symptoms have subsided; also in splenitis and psoitis of the left side. They generally lie on the left side, in pneumonia, bronchitis, and when effusion has taken place into the pleura of this side, and the pain has ceased. At the commencement of pleurisy, patients lie either on the back or in the semi-recumbent position, or on the side opposite to that affected, whilst the pain continues, and before effusion has become great; they also frequently prefer to lie on the back, or in a raised position, in organic affections of the heart and large vessels.

7. ii. THE EXPRESSION OF THE FACE AND STATE OF THE FEATURES.—The facial expression is of great importance in recognition, diagnosis, and prognosis of disease; and sometimes, especially in *children*, it is the chief means of evincing the nature of the malady. In them the appearances of the countenance may be observed with advantage whilst they are asleep, as well as when they are awake; and, in many cases, it is of use to observe the expression immediately upon awakening them. Although the experienced observer will be guided in his diagnosis by the expression of the face of children, yet he will generally find great difficulty in describing the appearances which thus influence his opinion.—*a*. The knitting of the *brows*, or frowning, in children usually indicates inflammatory irritation of the brain or membranes, or of both. And with this expression are often conjoined a contraction or approximation of the eyebrows and zygomatic arch. Relaxation of these parts, with a relaxation, drooping, or falling of the eye-lids, is a sign of vital exhaustion, or of effusion or pressure on the brain.

8. *b*. A *dark circle* surrounding the eyes, and most remarkable beneath the eyes, often with more or less sinking of these organs into their orbits, is often observed in connection with organic diseases, especially those of a malignant or contaminating nature. It is also very manifest in females who are subject to uterine or ovarian diseases, or to severe or prolonged leucorrhœa, or who addict themselves to masturbation. A *puffy or œdematous* appearance of the eye-lids, or below

the eyes, is observed in diseases of the heart, especially those implicating the valves, and in granular lesions of the kidneys, as well as in connection with several forms or seats of dropsy. Sudden or rapid *sinking of the eyes* inwards, with increase of the dark circle surrounding the eyes, is a most remarkable and most unfavourable sign in the stage of collapse of pestilential cholera, in an advanced stage of adynamic, hectic and malignant fevers, and in the last or most unfavourable periods of gastritis, enteritis, dysentery, and of purulent, tubercular, or cancerous contamination of the circulating fluids.

9. *c.* The *nose*, especially in connection with the *cheeks*—the *nasal* and *genal* expression—furnishes much information as to the seat and issue of disease, especially in children. A pinched appearance of the nose, with a retraction or dimpled state of the cheeks, often is observed in an advanced, or in an unfavourable, course of diseases of the digestive organs; and a remarkable dilatation and contraction of alæ nasi—a working of the nostrils, with or without retraction of the angles of the mouth, — attend not only the most dangerous forms or stages of disease of the respiratory organs; but most of those maladies in which the organs of respiration become more or less implicated at an advanced period, or towards a fatal termination. In severe or dangerous inflammation of the diaphragm, or of the serous membranes reflected over this part, those signs are most prominently manifested. The alæ nasi and cheeks are drawn upwards and outwards in the most painful and spasmodic affections of the digestive canal and diaphragm, especially in spasmodic gastralgia and enteralgia, in colic, ileus, and during the passage of biliary calculi.

10. *d.* The *lips* and *mouth*, with the chin, furnish important indications, — the *Labial signs.* — Retraction of the corners of the mouth, so as to produce the sardonic grin, is very remarkable when the diaphragm is inflamed or implicated in the manner just now stated, and in very painful and dangerous affections of the stomach, bowels, and tendinous aponeurosis. The lips are thin, retracted, or apparently stretched over the teeth and gums, in the last stage of hectic, especially when caused by pulmonary disease; the actions of the nostrils being also remarkable and unnatural. The face in these cases, particularly when emaciation has made great progress, is pinched in, retracted, and diminished, the chin becoming sharper and more prominent. The lips often are surrounded by a dark circle in chronic affections of the stomach, bowels, or liver. The lips lose their ruddy hue, or become more or less *pallid*, in anæmia, however produced, after hæmorrhages, in chlorosis, in diseases of the spleen, and in uterine and ovarian maladies. They often, at the same time, present a less erectile or tumid appearance, and are more disposed to crack, or become irritated or sore. Soreness of the lips and eruptions on them externally, are frequently observed in the course of chronic affections of the digestive canal, and abdominal viscera, especially in children at a far advanced stage of those diseases. The lips are often similarly implicated, but in a slighter degree and in a more fugitive manner, in connection with catarrhal affections. They often *swell*, especially the upper lip, in connection with latent or developed scrofula and tuberculosis; and in cases of intestinal worms. A *dark*, or a *purple hue*, of the lips, is generally present, when the blood is imperfectly changed to the arterial state, owing to disease of the lungs or heart, or of the respiratory passages, especially congestive bronchitis and broncho-pneumonia, or to effusions of fluid into the thoracic cavities. When this change of colour is observed in those maladies, it ought always to be viewed as a most dangerous appearance.

11. *e.* The *general expression* of the countenance may be bashful, down-cast, painful, anxious, terrified, enraged or joyful. — A bashful, downcast appearance, or an inability to look the person addressed fully in the face, is a certain indication of nervous exhaustion by masturbation and of impotency. This down-look in patients complaining of chronic disorders, or of diseases of debility, at once indicate the cause in which they have originated. — The expressions of pain and anxiety are readily recognised in connection with pain, extreme soreness, difficult respiration, palpitations of the heart, injuries, and inflammations of vital organs or parts. The expression of terror or extreme fear is observed chiefly after severe or dangerous accidents or operations, during excessive hæmorrhages, in rabies, in delirium tremens and insanity. The expression of rage occurs chiefly in mania, rabies, phrenitic delirium, and monomania. The countenance is vacant or unconcerned in true hæmagastric pestilence when it becomes also of a pale lemon colour, in amentia or idiotcy, and in general paralysis. It is tumid or bloated, all the features often appearing enlarged and exaggerated, in congestive and sanguineous apoplexy, in obstructive circulation from disease of the heart or valves, and in connection with dropsical effusions from such disease, and from diseased kidneys.

12. *f.* The *tint*, *hue*, or *colour* of the countenance furnishes important signs of disease. A pallid or anæmied hue of the countenance attends deficiency, thinness or poverty of blood, especially when observed in connection with pallor of the lips, gums and tongue; this state of the circulating fluid being either a primary ailment, or variously associated, or consecutive of numerous maladies—being thus either a *primary*, an *associated* or a *consecutive anæmia.*— *Primary* owing to inanition, to want of sunshine, light and pure air; — *Associated* with torpor, inactivity or exhaustion of the sexual organs, and characterized by a pale greenish yellow tint of the face, as in chlorosis; with disease of the uterus or ovaria; with tuberculosis of the mesenteric or bronchial glands, with disease of the spleen, or with wasting or structural lesions of the testes; — *Consecutive* of all fevers, of acute rheumatism, of inflammatory and structural diseases of the digestive organs, and of the absorbent system; and of tubercular and cancerous maladies.

13. A *dark*, *lurid*, or *murky tint* of the countenance is commonly attended by a similar hue of the general surface, especially in low, adynamic, typhoid or malignant forms of fever. It indicates a morbid condition of the circulating fluids, the blood being more or less contaminated and insufficiently changed from the venous to the arterial state. Along with this hue other tints may be associated, as that of *lemon tint*, as in

the hæmagastric pestilence, the features still retaining their fulness or plumpness; or a deeper *yellow* or jaundiced hue, as in severe bilious remittents, the features being more or less sunk; or a *greenish yellow*, or dark *green hue*, when the liver and biliary passages are completely obstructed, or the former disorganized throughout. A continued *sallowness*, or *murky pallor* of the countenance, is commonly an attendant upon torpor and chronic affections of the liver, and upon disease of the spleen. The face, the general surface, and especially the extremities and nails of the fingers and toes, assume a *leaden* or *lurid tint* in the stage of collapse of pestilential cholera; and this tint often becomes deeper and darker as the patient sinks, the features being collapsed, and the eyes sunk deep in their sockets. A livid hue of the countenance, most remarkable in the lips, and commonly with lividity of the nails and fingers, occurs in the last stage of pneumonia and general bronchitis, in congestion of the lungs, in obstructive diseases of the heart, and in dropsy of the thoracic cavities; and it is always a most dangerous, and generally a fatal sign.

14. A *pink hue* of the cheek, or a *pinkish red*, sometimes limited to the more prominent part of the cheek, is usually seen in hectic, especially the hectic of pulmonary disease. A generally diffused redness of the face attends inflammatory fevers, and is often observed during inflammation of the lungs, and occasionally in phrenitis. A persistent redness of the face sometimes occurs in persons advanced in life, who are accustomed to live fully or to drink port wine too freely, the features being usually at the same time large or developed. Redness of the face, with unusual fulness of the features, is often present in sanguineous apoplexy. The redness of the features which accompanies eruptive fevers is readily distinguished by the history and circumstances of the case, by the pulse and by the state of the general surface. A circumscribed patch of redness on one, or on both cheeks, is sometimes observed in chronic visceral diseases, and in low or hectic fever attended by alteration of the blood.

15. *g.* The *size* of the features generally—of the whole face—is often very considerably altered in disease. It is apparently *augmented* in sanguineous or congestive apoplexy, in acute mania, in phrenitis, and in convulsive diseases, especially epilepsy, in obstructive diseases of the heart, particularly those accompanied with dropsy, in acute and congestive pneumonia, and in the acute states of vascular action, observed in the hot stages of fevers,—periodic, continued, or exanthematous. — The size of the face is *diminished;* the features being shrunk or pinched, in the cold stage of periodic fevers, in pestilential cholera, in the advanced states of visceral disease attended by emaciation, especially of phthisis, and of hectic fevers. When the shrinking of the features becomes very remarkable in the advanced stages of either acute or chronic maladies, or approaches to what has been termed the *facies Hippocratica*, it is always a most unfavourable, and commonly a fatal sign.

16. iii. State of the General Surface of the Body. — *A.* The *colour* or *hue* of the surface frequently partakes of that of the countenance. Where the latter is ruddy, healthy and animated, the former is neither altogether pallid or white; nor dusky, lurid or dark, unless in the darker races. In the European, particularly of northern latitudes, the hue of the surface is that of white animated by a slight tint of carnation or pink. In the anæmied and chlorotic, and often in the leuco-phlegmatic and anasarcous it is pallid, or a dead-white, sometimes slightly tinted by yellow or pale yellowish green. The colour of the skin is more than naturally sallow, pallid or murky, in functional and organic diseases of the liver, spleen, often in chronic diarrhœa and dysentery, in obstructions of the mesenteric glands, and sometimes in organic diseases of the uterine organs. In the several forms of jaundice noticed above (§. 13.), the hue of the general surface is yellow, of various grades to a yellowish green, or even to a murky or deep green. A pale yellow, or lemon tint, with greenish or livid streaks or patches as the malady advances, characterizes hæmagastric pestilence; whilst a jaundiced yellow often attends remittent fevers, the tint becoming more deep or lurid, as the disease assumes more and more of a putro-adynamic character. The hue of the surface is dark, dirty or lurid in continued fevers of an asthenic or adynamic type; and it becomes darker or more foul as the disease advances, and as the powers of life sink. In the cold or formative stage of fevers, the hue is pallid, and the surface rugose, presenting the *goose-skin* appearance. As reaction supervenes, this disappears, and passes, with the increase of reaction, into the warm and carnation glow of health. When, however, no such healthy reaction occurs, as in adynamic, typhoid, putro-adynamic and pestilential fevers, the pallid hue of the general surface passes into a lurid, harsh or foul appearance; and this, either becomes deeper and more remarkable, or, as in the choleric pestilence, assumes a peculiar leaden or livid aspect, as the malady approaches a fatal issue.

17. *Deeper or other discolourations* of the skin are either partial — in spots or patches; or more marked in some situations than in others. These consist either of very limited exudations of the colouring particles of the blood under the cuticle, in one or other of the tissues composing the skin, or of exanthematous or other eruptions. The former constitute the characteristic of purpura, of scurvy, and of some forms of fever. When the vital cohesion or tone of the capillaries is relaxed in certain tissues, as in the vascular rete of the skin; and when, at the same time, the healthy crasis of the blood is much impaired, as in those maladies, minute exudations, containing more or less of the colouring matter of the blood, take place, in the form either of punctæ or of larger spots or even patches; and, according to the states of vital power, and of the exuded fluid, present various hues, from a bright or scarlet red, to a livid or blackish colour— *petechiæ, vibices, &c.* (*See Art.* Fever, §§ 470, 471.). These seldom undergo further changes unless in the extremities, where, from neglect or improper treatment, the exudations may be followed by ulceration, especially in scurvy, and by sphacelation, as in the putro-adynamic states of fever.

18. *B. The Eruptions* on the surface of the body furnish most important indications as respects not merely the nature of the disease, but also its pro-

gress and issue. Exanthematous, acute and chronic, eruptions have been very fully discussed in the several articles on the diseases which are characterised by them. It is hence unnecessary to take further notice of them, than to remark, in general terms, that the less general or copious the eruption, and the less the functions of the skin are impaired by it, the more may the result be considered favourable; and that the more diffused, general and confluent the eruption, and the deeper the colour, the more unfavourable should be the opinion as to the issue. As respects all eruptions, but more particularly as regards the exanthematous, deepness of hue, — lividity or darkness of colour, — should be viewed as being much more dangerous than the amount or extent of eruption; for, even when extensive, the risk may not be materially increased as long as the hue is that of a lively red; but in proportion to the deepness of the tint, and as it approaches to lividity or blackness, the danger becomes extreme.

19. *C. The temperature of the surface* varies remarkably with the grades of vital power and of vascular action; and the character of the temperature is much modified by the state of the perspiratory function. — (*a.*) A general *depression* of temperature often attends sinking of vital power; and when this sinking becomes extreme it is commonly accompanied with cold perspirations, which are most remarkable in the extremities, as in the last or fatal period of most diseases, and over the whole surface in the choleric pestilence; the depression of temperature being also great, especially in this malady, and manifestly increased by the evaporation of the perspired fluid. — Coldness of the surface ushers in many febrile and inflammatory diseases — especially the cold stage of periodic fevers, and of visceral inflammations; but the coldness in these maladies exists more in the mind of the patient, than to the perception of the physician; and it is generally attended by peculiar phenomena and sensations — by chilliness, horripilation, shivering, rigors or horrors, which may be viewed as grades of the same sensation, and which are accompanied with a remarkable feeling of cold extending from the occiput along the spine, and with constriction and dryness of the integuments. In these cases, the sensation of coldness, when thus characterised — by horripilation or shivering — is altogether morbid, the temperature of the general surface either not being depressed, unless in the extremities, or being sometimes even much increased, especially over the trunk. The sensation of coldness and the shivering, both in these maladies, and in cases of internal abscess, or where matter is being formed, are to be imputed chiefly to the concentration of the morbid action internally, or to the determination of the circulating fluids to internal or vital organs, and but partially to the diminished temperature of the extremities and surface, and to the constriction of the integuments; for, even when the sensation of coldness or chilliness is very considerable, and the horripilations amounting even to shivering, the heat of skin, especially over the trunk, may be excessive; but in these cases the surface is not only hot, but also dry and constricted; and either reaction is being about to be developed, or a copious perspiration is about to supervene, as when these symptoms indicate the formation of an internal abscess. When they occur in very aged persons, and depend neither upon the invasion of a febrile paroxysm, nor upon any visceral irritation or *inflammation;* and even when, in those persons, they recur at intervals, and alternate with sensations of heat or flushing, they are dangerous symptoms, generally issuing in dissolution.

20. (*b.*) The coldness of the surface, whether actual, or existing chiefly in the sensations of the patient, whether marking the invasion of a febrile paroxysm, or the commencement of inflammatory action, or the formation of abscess in an inflamed organ or part, should be viewed chiefly as a change in the state of organic nervous power or influence upon the vascular system; this influence being more or less depressed or impaired in the extremities and periphery of the frame, and either determined to, or increased in vital or internal organs, the vascular system being similarly affected, owing to the organic nervous influence on it. If this influence be so powerfully impressed as to be incapable of restoration, or so overwhelmed by the cause impressing it as to sink progressively, coldness of the surface becomes more general, more manifest and actual, and death ultimately takes place; but, when the organic nervous or vital influence is morbidly impressed, without being overwhelmed or destroyed altogether, the concentration of that influence in vital organs, or the remains of it in these, enable them to react upon the blood which is superabundantly returned or determined to them, and thus the circulation is kept up, and secretion and excretion are promoted, until the morbid impression and its various consequences are removed. One of the earliest of these consequences is depression of the animal temperature, with constriction of the integuments, which is followed by reaction when the vital influence is not altogether overpowered. According to the nature of the morbid impression, or of the irritating cause, the temperature of the surface, and the sensations and other phenomena characterising the state of the cutaneous surface, vary remarkably: and, whilst the temperature may be absolutely lowered, with or without a sense of chillness or coldness, or horripilations, in some cases, with shivering or rigors in others, and even with horrors and distressing tremors; it may not be materially depressed, unless in the extremities, these attendant phenomena occurring nevertheless. The rigors, and the still more severe manifestations of tremors or horrors, are indications of the severity of the morbid impression, or of the cause of irritation on the nervous system, and more especially upon the spinal chord and nerves proceeding from it. We often observe irritation of mucous or serous surfaces, by various causes, as by the passage of a calculus along a duct, and even by the introduction of a catheter or bougie along the urethra followed by constriction and coldness of the surface, by horripilations or rigors. In these cases the cause of irritation, acting upon a single part of the circle of organic nervous endowment and influence, disturbs the healthy distribution of the blood, depresses or diminishes the circulation in the periphery of the frame, concentrates it towards internal parts, whilst the irritation existing in a part of the organic nervous system is propagated by communicating nerves to the spinal chord, or to

the roots of the spinal nerves, and is reflected thence by the spinal nerves to the muscles of voluntary motion, occasioning rigors, tremors and horrors, which cannot be controlled by volition, until the more general diffusion of the primary morbid impression or irritation, and the reaction and the consequent equalisation of the circulation remove the morbid effects extended to the spinal nerves and the muscles supplied by these nerves. (See §§ 22. *et seq.*)

21. Coldness of the surface of the body is attended by various modifications, as respects both the sensations of the patient and the perception of the physician, according to the cause which produces it, and to the function or state of the skin at the time. When the coldness proceeds from depression or irritation of organic nervous influence, in connection with manifest disturbance of the circulation, then the surface is generally also dry and constricted, as in the invasion of diseases proceeding from causes which primarily simply depress or irritate; but when, with this change in the nervous system of organic life, there is also loss of vital tone or cohesion — when, owing to the excessive irritation or depression, or to the loss of vital cohesion, or to poisonous contamination, there are also relaxation of the integuments, and increased perspiration, then the coldness of the surface is not merely augmented, but it is characterised by a peculiar sense of rawness as well as of coldness — partly augmented by evaporation, and partly by impaired circulation. Colliquative perspirations which are not consequent upon heats or flushings, and the state of the surface in the last stages of low fevers, in the choleric pestilence, and after poisoning by numerous depressing, contaminating and irritant poisons, furnish various modifications of this condition.

22. (*c.*) *Increased temperature* of the surface is an important sign of disease, whether it occurs primarily, or consecutively of more or less depression; and, according to the character of the increased heat, so may not only the state of vascular action be partly inferred, but also the condition or amount of vital power and resistance. Heat of the skin is rarely so great, when it occurs primarily as when it supervenes upon chills or rigors. In the former case, it is more moderate, generally subsides sooner; and, unless when it is caused by the infection of some animal poison, is more free from other morbid phenomena manifested in the general surface. When heat of skin follows rigors, the reaction of the vascular system, upon which it chiefly depends, influenced however by the organic nervous power, carries the temperature several degrees above the standard of health, and this high range is often increased or prolonged by the constriction and dryness of the skin, and by the morbid state of the blood itself — morbid in consequence of deficient action of the emunctories during the preceding depression, coldness, chills and rigors; the augmented quantity of effete materials in the blood irritating the blood-vessels and vital organs, and morbidly exciting the nervous system of organic life. The result, as respects the surface and integuments, is not merely an increase of temperature, but also, and chiefly, owing to the dryness of the skin, and to the state of the circulation now mentioned, a peculiar sensation imparted to the hand of the observer, and characterised by a harshness, acridity or burning, and sometimes by a feeling of stinging or tingling to the patient himself.

23. When the circulating fluids are not greatly altered or contaminated, and the organic nervous influence not seriously depressed or perverted, the excitement of the vascular system, producing augmented heat of surface, gradually subsides, and with it this particular effect. As the excited vascular action abates so the skin relaxes, secretion and excretion, in the several emunctories, either returning or increasing, and with the return of the functions of the skin, the temperature of the surface falls. A fit of ague furnishes an apt illustration of the states of the surface of the body in different febrile and other morbid conditions of the frame; and of the succession of these states, and of the influence of the antecedent, in producing the consequent condition.

24. A harsh, fiery or burning heat of surface is always an unfavourable sign, especially in visceral inflammation; and if, at the same time, the patient complains of a sense of burning at the præcordia, or of internal heat, with anxiety, jactitation or restlessness, the extremities becoming cool or cold, or being covered by a cold perspiration, a fatal result, especially by gangrene, may be expected. Increased heat of head indicates frequently a disposition to apoplexy in the aged, to inflammation of the brain or its membranes in the young and middle-aged, and to convulsions or meningitis in children. A burning or acrid heat of surface in the hot stage of periodic, and of hectic fevers, augurs a malignant or dangerous form of the one, and a fatal termination of the other, especially when diarrhœa is also present, or when the heat of skin is followed by excessive colliquative perspiration. The temperature of the surface is always highest over a sthenically inflamed organ; and, as respects the extremities, it differs more or less in different sides in hemiplegic or partial paralysis, as shown when treating of that malady.

25. iv. THE PERSPIRATORY FUNCTIONS of the skin are variously affected by disease, and aid more or less in evincing the nature and the result of the malady. Interruption to, or entire suppression of, the perspiration, as shown by dryness of the skin in the earlier stages of fevers, and of inflammations, is of much importance as respects the states of the circulating fluid and of vascular action. This state of the surface may be attended by depression of temperature (§§ 19. *et seq.*), as in the cold stage, or in the invasion of these diseases, or by increased temperature (§§ 22. *et seq.*), as in the hot stage, or when vascular action is excited; but, however associated, or accompanied by each in succession, suppression of the perspiration is indicative of the invasion or commencement of fever or of inflammation, when attended by coldness of surface or by chills or rigors, and of a farther advanced state of these maladies when the skin is not only dry but also hot. The amount of dryness, and of either coldness or heat with which dryness is associated, and the duration of these states of the surface, are matters of much importance in our estimation of the nature and extent of disease, and of the probable issue; for if the suppression of the excreting function of the skin be more or less complete, and of considerable dura-

tion, and no other excreting organ or emunctory supply vicariously the defective function, — if the injurious elements and materials usually eliminated by the skin, are not partially or altogether carried out of the blood by other organs, it must necessarily follow, that the prolonged suppression of the perspiratory function will contaminate or poison the blood; and that the primary or local disease will be thereby exasperated, or a morbid state of general vascular action will be developed, varying with the changes produced on the blood by the other emunctories, and giving rise to further alterations, both functional and organic.

26. *A. A perspirable* and *humid state* of the cutaneous surface, when attended by a soft, natural, slightly unctuous and moderately warm condition of it, is always a very favourable sign, especially when it is general, and not limited to a single region or part; but, when the perspiration is spontaneously excessive, and results not from unusual exertion or from medicine, &c., more or less disorder, sometimes of a very dangerous nature, is then present. The *quality* and *odour* of the perspiration require attention, as well as the quantity; and the circumstances and occasions of excess ought also to be noted. It should not be overlooked, also, that the cutaneous perspiration is not always or altogether suppressed when it is no longer manifest to the senses; for an insensible perspiration generally exists, which may vary with the state of the patient, with the temperature of the skin, and with the dryness, humidity, and electrical states of the air. The perspiration which may be insensible in dry states of the air, may become sensible, or collect on the surface, in the form of sweat, when the air is moist and relaxing. During health the perspiration is more insensible than sensible, and along with the exhalation of fluid from the surface, a secretion takes place from the follicular apparatus of the skin, which softens, and even partially lubricates the cuticle, especially in the negro race, and promotes both the insensible and sensible perspiration by disposing the surface to the transmission of its accustomed exhalation. The sensible and the chemical qualities of the perspiration vary considerably in different regions of the body, owing partly to the greater admixture of the secretion from the follicular or sebaceous apparatus. The difference is most manifest in respect of the perspiration from the axillæ and the groins, &c., the organic or solid constituents being most abundant in the sweat of these regions. But before any notice should be taken of morbid states of the perspiration, the healthy condition of this excretion ought to be mentioned.

27. *B. In health*, the perspiration, when too copious to be carried off in the atmosphere, without becoming sensible, or in the state of insensible vapour, is condensed in the form of fluid, or *sweat*; 1000 parts of which consist of from 993 to 995½ of water (Anselmino, Berzelius, Simon, &c.). The remaining solid constituents consist— 1st. Of substances soluble in water, — watery extract, phosphate of lime, and occasionally an alkaline sulphate. — 2nd. Substances insoluble in water, — desquamated epithelium, and, after the removal of free lactic acid by alcohol, phosphate of lime, with a little peroxide of iron.— 3rd. Substances soluble in ether, — traces of fat, sometimes including butyric acid. — 4th. Substances soluble in alcohol, — alcoholic extract, free lactic acid, and acetic acid, chloride of sodium, lactates and acetates of potash and soda, lactate and hydrochlorate of ammonia. In addition to carbonic acid, nitrogen is exhaled from the surface in constant but varying proportions, according to the nature of the diet and the amount of exercise. The functions of the skin may be divided into — 1st. The *Physical*, — the exhalation of pure water and gas. — 2nd. The *Organic*, — the product of animal excretion, or the secretion of cells. The cutaneous excretion is in antagonism with the pulmonary, with the urinary, and with the intestinal; an excess of either diminishes more or less the amount of it.

28. *C.* The *amount* of the insensible and sensible (sweat) perspiration has been variously estimated in health, but not with that approach to precision which would warrant a positive statement. It it very remarkably increased or diminished *in disease*, the diminution being more difficult of estimation, than the increase. In the cold states of disease, the diminution may be very remarkable, or scarcely to be estimated, and, in some cases, as in those characterised by sinking vitality, the perspiration may be excessive, as observed in pestilential cholera. In hot states of the surface, the temperature may prevent a more than natural transpiration from being condensed into a sensible fluid, the perspiration being excessive and yet being insensible. But whether sensible or insensible — whether diminished or increased, but more remarkably when increased, the perspiration is attended by very different kinds of *odour*, the odour often depending upon the chemical constitution and organic constituents or elements of the excretion, and being generally peculiar to each specific disease, although different observers have described the odours differently, or have assigned to them different resemblances.

29. The *increase of sweat* is very remarkable, not only in different maladies, but also in different periods of the same malady. Thus, while perspiration is diminished or almost suppressed in the cold and hot stages of ague, it is remarkably increased in the sweating stage. The same is observed in the paroxysms of hectic, in remittent fevers, and in continued fevers, but in prolonged stages, and even in inflammations. The most remarkable increase occurs in acute rheumatism, in the advanced stages of pulmonary consumption, in pestilential fevers, and in most maladies characterised by sanguineous contamination or poisoning, or infection of the fluids; and, in these especially, the *quality* and the *odour* of the perspiration are much altered.

30. *D.* The *quality* of the sweat is changed in most febrile diseases; but the change of quality, with reference to each, has not been satisfactorily shown.— *a.* The free *acids* may be much increased. Lactic acid, the ordinary free acid, is usually more abundant than in health, in cases of rheumatism and gout, and probably, also, uric and acetic acids. Dr. Prout detected the last in hectic fever, and both it and lactic acid may be present in the puerperal states of fever and in erysipelas. Anselmino found free acetic acid in women during their confinement, and Stark, an increase of the lactic acid in scrofula, rickets, and in several cutaneous eruptions.

31. *b. Ammonia* does not appear to exist in the

sweat in a free state, but chiefly in the state of lactate or hydrochlorate, although it may be found soon after the fluid is excreted, and during its retention in the armpits and groins. As to the actual presence of ammonia in the perspiration during disease, the statements of chemists and other observers are devoid of precision; for we still require to know whether or no the ammonia exists in a free state at the time, or even after the formation of the sweat, or, whether it is evolved by the combination of the acid which neutralizes it with another base. ANSELMINO found a larger proportion of ammonia in the sweat after an attack of gout than in any other case. BEREND states, that the sweat in putrid and typhoid fevers is ammoniacal. That it sooner becomes ammoniacal in these maladies than in any others, owing to a greater amount of animal matter contained in the perspiration, appears to be nearer to the truth. It may, however, be admitted, that all sweat of a putrid odour either contains free ammonia, or sooner becomes ammoniacal. According to NAUCHE, the sweat in nervous diseases soon becomes alkaline. On this, and other topics connected with the chemistry of the secretions and excretions, SIMON and others are loose in their statements and in their authorities.

32. *c.* The *salts* are often much increased. PROUT observed a great increase of the chloride of sodium. After attacks of gout, and in the gouty and rheumatic diathesis, the phosphates of lime, as well as the urates, are increased as respects either their proportions in the sweat, or the absolute quantity excreted. In critical, and in colliquative sweats, the proportion of the usual solid constituents differs remarkably, although the amount of difference is not ascertained; and there is every reason to infer, that in these, and in exanthematous, low, putrid, and pestilential maladies, there is a considerable change, especially an increase in the fatty, extractive, and saline ingredients of the perspiration; and that, moreover, substances not usually found in the sweat, may, in these diseases particularly, be detected in it. ANSELMINO and STARK say, that *Albumen* has been found in the perspiration in cases of rheumatism, and in gastric, putrid, and hectic fevers. *Fat* has been found in the perspiration in colliquative and low maladies by myself in several cases; *uric acid* and urate of soda have been detected in the sweat of arthritic persons, and cases of gravel; *bilin* and *biliphæin*, in the perspiration of persons who are jaundiced; and the red colouring matter of the urine, *Uroerythrin*, in the perspiration in rare cases of fever. The colouring particles of the blood have been seen in the perspiration in scorbutic cases, and in putrid and pestilential maladies, in rare instances.

33. *d.* Various substances foreign to the œconomy have been detected in the perspiration after their ingestion. The chief of those are sulphur, mercury, iodine and iodides, assafœtida, garlic, saffron, indigo, prussian blue, turpentine, &c. These may be partially altered, or combined with other materials; and many other substances, even when digested, during their partial excretion by the perspiration, or by means of certain of their constituents, impart an odour to this excretion, by which even the nature of these substances may be recognised. Although these circumstances are of little importance as signs of disease, yet they should be held in recollection when the *odour* of the perspiration is estimated as a means of recognising certain maladies, and they ought to be viewed as furnishing proofs of the part which the skin performs as an excreting organ.

34. *E.* The *odour* of the sensible and insensible perspiration has not been sufficiently attended to, in the recognition and diagnosis of disease. An experienced and closely observing physician will often at once perceive the nature of the malady, from the *odour* of the effluvium proceeding from the body of the patient, even before he may have seen it or approached it. This is especially manifested by exanthematous and pestilential fevers; and although many, whose sense of smell is not acute, are incapable of distinguishing disease by this sense, others are often at once thus enabled to recognise the nature and even the progress of the malady. Most of those specific diseases which are propagated by the effluvia proceeding from those already suffering from them by infection, impart a more or less peculiar, and generally an offensive odour; and although this odour and its resemblances may be familiar to the observer, yet he will rarely be able to describe it in terms which will make it accurately known to another. The effluvium from persons in pestilential cholera is especially offensive and sickening, and it always imparts a sense of depression to those who perceive it. That from small-pox, or scarlet fever, or measles, differs from each other, or is peculiar to each. The odour of the sweat of persons in putro-adynamic fever and scurvy is generally of a putrid character. That of rheumatic and gouty persons is usually acid. Females in puerperal fevers exhale a peculiar sweetish acid odour. Persons whose intestinal excreting functions are insufficiently performed — whose bowels are much confined, are often subject to a particularly offensive, as well as an increased perspiration. The determination of the odours of the perspiration in diseases is, however, quite subjective, and different observers generally describe them by different resemblances, which are not always assigned with accuracy. Thus the perspiration of persons with itch is said to have a mouldy odour; that of scrofula to resemble the smell of sour beer; that of syphilitic patients to have a sweet odour; and that of ague is said to smell like fresh-baked brown bread. The odour of the perspiration in disease, especially in respect of infection, has been imperfectly attended to, although deserving of attentive observation.

35. *F.* The *other sensible or physical qualities* of the perspiration consist chiefly in those which have been partly noticed when describing its chemical conditions. An acid or an alkaline state of the sweat may readily be ascertained by the usual test-papers; but the acid or alkali present is determined with much greater difficulty. The appearance of the linen generally shows the presence or absence of the colouring matter of the bile; and even common bibulous paper will often demonstrate the existence of fatty or oleaginous matters. A watery and copious sweat is commonly produced, in the previously healthy, by exertion, by increased temperature, and by diseases of simple vascular excitement, when the other emunctories are duly discharging their functions. In these circumstances, the perspiration is warm, copious, watery, and without mor-

bid odour. In low, putro-adynamic, colliquative, and pestilential maladies, the sweat may be abundant, thick, clammy, cold, and variously altered in chemical constitution, especially in the amount of animal extractive matters, in epithelium scales, in saline ingredients, in odour, and in the changes it evinces soon after being collected; but in all these particulars, further and more accurate observations than we yet possess are required.

36. v. THE NUTRITION OF THE BODY is one of the first circumstances which attracts the attention of the physician; the character as well as the amount of nutrition appearing to him of great importance. The diminution or abundance of adipose substance; the amount of emaciation or of obesity; the size and tone of the muscles; the rigidity, firmness or flaccidity of the flesh; the colour and state of the integuments, and the presence or absence of intumescence, œdema, anasarca or leucophlegmasia, are appearances which always interest the medical observer. — *A. Emaciation* is, when very remarkable or excessive, of great consequence in our estimation of the nature and ultimate issue of disease. In all cases when it is considerable, and especially when very great, it requires close consideration in respect both of its causes and of its morbid relations. — *a.* Emaciation increases rapidly in low, continued, remittent, and hectic fevers, the degree of emaciation, and the rapidity of its progress indicating the severity and danger of the malady. In organic diseases of the lungs, stomach, and digestive organs generally, emaciation is always present, the acceleration of its course, and the degree to which it has advanced, furnishing proofs of the danger to be expected, especially when it is attended by quickness of pulse and other febrile symptoms. In acute or febrile phthisis, the rapidity and the extreme degree of emaciation are amongst the most prominent and fatal indications furnished by the malady, and may be the most remarkable when cough and expectoration are the least observed. In all diseases which tend to inanition — in structural changes in the œsophagus, cardiac and pyloric orifices of the stomach, and in the mesenteric glands, emaciation advances more slowly, but to an equally great extent. In the more chronic states of phthisis, in diseases attended by augmented secretion or morbid discharges, emaciation is slower in its progress, but it also becomes extreme, if the malady receives no check, or is not removed by treatment. In continued fever emaciation seldom is apparent until the period of vascular excitement subsides, but after this period it advances rapidly — the more rapidly the greater the danger, more especially in the intestinal or gastric complications of fever. When with rapid or extreme emaciation there is also a dusky, lurid or livid hue of the surface, the danger is very great; and if eschars, &c., form on parts which are pressed upon, it is still greater.

37. *b. Partial emaciation* is observed chiefly in paralysed limbs or diseased parts, and depends upon the inaction of the muscles of these parts for a long period. In many cases the muscular emaciation is concealed by a degree of œdema or leucophlegmasia, which often affects the paralysed limb. In all cases, therefore, it is of use to know to what extent the emaciation is that of the adipose tissue, or of the muscular structures. In the slighter forms the adipose tissue only is diminished, whilst the muscles are but little diminished, but in extreme cases the muscles also become extremely flabby and ultimately wasted.

38. *c. Arrest of the progress* of emaciation, and a more or less marked restoration of the flesh, and especially if there also be a restoration of strength and of the natural hue of the surface, are amongst the most favourable indications of returning health, and of the removal of the pathological conditions upon which emaciation depended. *The superabundance* of adipose tissue is noticed in the articles ADIPOSE TISSUE, and OBESITY.

39. *B. Flaccidity* of the soft-solids of the body may precede or accompany emaciation, or even œdema, anasarca, &c. But, however attended, it is always an indication of debility or exhaustion, and often in connection with impaired nutrition. In fevers, especially flaccidity of flesh, is attended by discolouration of the surface (§§ 16, 17.), and, as they proceed, by alteration of the blood, especially as respects the hæmato-globuline and saline constituents, by anæmia, by absorption of the adipose substance and emaciation. During low fevers, and in the more inflammatory states of fever, after the stage of vascular excitement has abated, flaccidity of muscles, absorption and emaciation proceed rapidly. Nutrition is arrested from the commencement of the malady; and, although the arrest is not manifest at an early stage, it has nevertheless taken place, the capillary turgescence, arising from febrile or vascular excitement, preventing it from being apparent.

40. Where flaccidity is most remarkable, emaciation not having advanced far, the flesh has often unnatural *softness*, especially in the leucophlegmatic temperament; and in some cases, the softness and flaccidity are either unattended by apparent emaciation, or characterised by turgescence, the unanimated or partially discoloured hue of the surface, suggesting the idea of an unhealthy, watery, or semi-liquid state of the adipose and cellular parts below the integuments. This condition is intermediate between the natural and the œdematous or anasarcous state, and is aptly called *leucophlegmasia.* When partial it often passes into œdema, intumescence being then very considerable, the surface *pitting* from pressure; and when more general it may pass into *anasarca*, the watery effusion into the cellular and adipose tissues being such as to produce great distension of the integuments, with pitting, &c. This *leucophlegasia* is always an important sign of disease; and is often attended by anæmia, or rather by poorness of the blood — by a deficiency of hæmato-globuline. When this state is very marked, whether there be emaciation or intumescence, chronic disease of the digestive and assimilating organs may be inferred, and consequently impaired or morbid nutrition. Attention, in these cases, ought to be directed not only to these organs, but also to the functions of the kidneys and to the cardiac signs. In females, the uterine functions are generally more or less disordered, when this sign of disease is present, and when there is also a yellowish or jaundiced tint of surface, organic change in the biliary apparatus may be inferred, which commonly terminates in ascites, or even in more general dropsy.

41. vi. The ORGANS OF VOLUNTARY MOTION—

the locomotive organs — are variously and seriously affected by disease, owing chiefly to the states of the nervous centres, by which the muscular apparatus is actuated, but, in many maladies, to the conditions also of organic nervous energy of the muscles themselves, and of the blood. Loss of motion or of sensibility, or of both, in a part, or in one-half, or in the whole of the body, has been fully treated of under the head PARALYSIS. But the locomotive organs may be more or less paralysed, or similarly affected, in maladies which have not been usually termed paralytic. — *A.* In adynamic, putro-adynamic, typhoid, typhus, and exanthematous fevers, the loss of muscular power is very marked, even from the commencement; and in these maladies it is not to be so much imputed to the state of the brain, spinal chord, and their envelopes, as to that of the organic nervous system, the muscles themselves, and ultimately the blood, being influenced by this system. So remarkably are the locomotive organs affected, in these, and in all low or malignant fevers, as to render them incapable of retaining the standing or sitting positions, or even a position on either side, the patient being constantly supine. The degree in which voluntary muscular power is prostrated is remarkably great in all these fevers, the amount of danger being partly manifested by the degree of prostration, and the inability to lie on, or turn to, either side. Amongst the most favourable and earliest signs of recovery is the return of the power to lie upon either side, and afterwards the capability of turning from the one to the other. (§§ 4, 5, 6.)

42. *B.* But muscular power is not only *lost* or *prostrated*, in the modes evinced by palsy and low fevers, but is also otherwise affected, and in various ways. Owing to changes implicating the nervous centres of animal life, the muscles are frequently capable only of imperfect, uncertain, indeterminate, or irregular contractions; the motions of the limbs or members being similarly characterised. These morbid states of voluntary motion are apparent only upon efforts at locomotion, or on volition; but other morbid states of motion occur and continue in opposition to volition, and consist — 1st. Of continued tremor; — 2nd. Of frequent, or continued contraction and relaxation, with uncertain or imperfect voluntary motion, as in chorea;—3rd. Of spasm or cramp, of short or momentary duration; — 4th. Of spastic or permanent or continued contraction of one or more muscles; — 5th. Of more or less general spasm, followed by partial or more general relaxation or irregular action, as in epileptic and convulsive seizures; — and 6th. Of continued general spasm, as in tetanus. These states of locomotive function present numerous associations and relations, which serve both to characterise specific forms of disease, and to indicate the issue of the disease in which they are observed.

43. (*a.*) The *prostration* of muscular power observed in low fevers is always attended by flaccidity of the muscles, indicating impaired rigidity and tone of the muscular fibres, and loss of irritability; and by a harsh, discoloured, or lurid hue of the surface, evincing a morbid state of the blood, and of the functions of the capillaries. These states show the propriety of having recourse to such agents as will most efficiently promote or rouse organic nervous energy, restore the excreting or depurating functions, and counteract the morbid or contaminating changes taking place in the blood. Unless the conservative influence of life be supported by these measures — unless vital resistance to contaminating or hurtful influences be thus promoted, prostration of muscular power, and sinking of vital function, proceed with increased celerity, and soon terminate in dissolution; a favourable crisis, taking place on some occasions only, by means of vital resistance, and the spontaneous action of an important emunctory thereby developed under the favourable circumstances of locality, of constitution and age.

44. (*b.*) The *imperfect and indeterminate contractions* which follow volition are generally occasioned by exhausting discharges, by masturbation or premature or excessive sexual indulgences, and are followed by general palsy, and often also by imbecility. The general palsy of the insane is of this nature, and, although life may be protracted for years, it is generally shortened in the manner shown in the articles on INSANITY (§ 170.) and PALSY (§§ 65. *et seq.*).—In these cases the cerebro-spinal centres are often more or less wasted or altered in their intimate organization; and frequently little or no aid is derived from medical treatment, or even from diet or regimen.

45. (*c.*) *Continued tremors*, or constant shaking of a part — of the head, of an extremity or limb, &c., — or frequent twitchings of a muscle or part, are commonly indications of irritation at the origins of the nerves supplying the affected parts, or of some changes disturbing these nerves. When this sign consists of either shaking or tremor, it may continue for many years, the patient often reaching the usual duration of human existence; but it is rarely or never controlled by medical treatment, although life may be prolonged by a regular and abstemious regimen and diet. The *twitchings* which sometimes affect one or more muscles, especially the muscles of the face, are generally much more serious signs, and although they may continue for years, yet they generally terminate sooner or later in apoplexy or palsy.

46. (*d.*) *Cramps or spasms* may depend upon irritation of the bowels by acidity or flatulence, and, when they affect the lower extremities in the gouty diathesis, they generally proceed from this source, and are often connected with the presence of morbid or effete matters in the circulation. More *permanent or protracted spasms* generally proceed from inflammatory action in those portions of the nervous centres where the nerves originate that supply the contracted muscles; and these are often the forerunners of palsy, are sometimes associated with palsy of adjoining parts, or of opposite limbs, and are often followed by apoplexy or coma.

47. Cramps or spasms, varying in character with existing pathological conditions, occur in various diseases. They often effect the muscles of the lower extremities, when the intestinal canal is violently irritated, and often also the abdominal muscles. Although indicating a severe state of disease, they are seldom attended by danger unless they extend to the superior extremities, or are symptomatic of pestilential cholera, or of the ingestion of acrid, or of irritant and depressing poisons (see Art. POISONS, *pleuries*). When they occur in the course of phrenitis, of apoplexy, or

of palsy, they are unfavourable symptoms, and indicate at least a severe form of disease, passing into organic changes in parts of the nervous centres. They are also most serious indications when they occur in fevers and in puerpural females. The same remarks apply to *convulsions* appearing in the circumstances now mentioned, unless they are symptomatic of hysteria. (See Arts. CONVULSIONS, EPILEPSY, HYSTERIA, &c.)

48. Muscles are sometimes singly affected, or the affection extends merely to such muscles as are supplied by a single or by a pair of nerves; and the affection may be either that of *paralysis*, or of *spasm*, or the latter followed by the former. These partial or limited affections are often important indications of the early stages of structural changes in those parts of the nervous centres connected with the origins of the nerves supplying the affected muscles. When one or more of the muscles of the face are thus affected, unless a manifest cause exists in the course of the nerves supplying them, then more serious results may be expected, in the form either of apoplexy, or of convulsive coma, or of more complete or general palsy. If the muscles of the tongue or of the pharynx be implicated, in either of the modes just stated, structural changes at the origins, or in the course of their nerves, may be inferred, which will sooner or later terminate in an apoplectic seizure, or in hemiplegia. When these muscles are so affected as to prevent articulation, or deglutition, or both, an apoplectic attack, rapidly terminating in death, generally ensues after no very long interval. Prolonged spasm or contraction of the hands or feet, or of both, is observed in infants and children, in connection with cerebral disease, and often also with laryngismus: it is always a very dangerous symptom.

49. Muscular movements are affected by disease in every form or grade from complete loss of the power of contraction, to impaired weak, or irregular or uncertain contraction, involuntary twitchings, clonic or atonic spasms, or convulsive movements, spastic or protracted contractions, and tonic or tetanic contractions of a prolonged and general kind. These grades of diseased muscular action are not progressive; they are seldom consecutive or progressive, but one or other generally appears independently of the rest, and, if one state or form supervenes on the other, that of spasm is most frequently followed by paralysis, this latter being rarely followed by spasm. These several and very different forms of muscular affection are common in infants, in children, and are not infrequent in adults and aged persons. In young subjects, especially in children, they are more frequently sympathetic, of irritation of the digestive canal, of teething, of intestinal worms, although sometimes proceeding more directly from alterations in the nervous centres or their envelopes; whilst in adults and aged persons they more frequently arise from these latter morbid conditions. But whatever changes of a structural nature may induce them, they may severally appear in different or even in opposite states of the vascular system — in states of anæmia or deficiency of blood, or of natural fulness, or of excessive plethora; and these different conditions of the vascular system are not especially allied to particular forms of disordered muscular action, for, with vascular anæmia, loss of motion, or impaired or uncertain motion, or clonic spasm, or convulsions, or even protracted spasm, may take place, although clonic or atonic spasm or convulsion is the most common. The same remark applies to other states of the vascular system, for, even when loss of motion may be most complete, vascular fulness may be greatest, and, even when spasms are most general and protracted, as in tetanus, and in its several modifications, the vascular system may be equally exempt from deficiency and fulness of blood. All disorders of the muscular movements require close observation and most particular investigations into the pathological states producing them. They are of most serious import, especially in adult and aged subjects, unless when symptomatic of hysteria or gout, and even then they ought not to be undervalued; and, unless they are referred to inflammatory action in some part of the nervous centres or thin envelopes, they are seldom benefited by large vascular depletions; or, if depletions be indicated, they ought to be employed with caution, those which are local or derivative being the most serviceable. Much more frequently very opposite means to vascular depletions are required, especially tonics, antispasmodics, stimulants, &c., variously conjoined with other means, according to the changes inferred in each form of these disorders, and in each case which comes under treatment.

50. C. *The joints and ligaments* furnish signs which are intimately connected with constitutional diathesis, and with disorders of the digestive and vital organs. In the gouty and rheumatic diathesis, they are not only the most frequent seats of disease, but also the parts to which attention should be directed in forming an opinion as to the recurrence of disorder or the means of averting it. A tumid condition of the joints, and relaxation of their ligaments, whether appearing singly or in conjunction, are certain indications of predisposition to disease, even when little disorder besides is manifest. The former of these, especially when associated with a marked development of the lymphatic system, or with enlargement of the glands, or fairness of skin, &c., is a certain sign of the scrofulous diathesis; whilst the latter is connected with constitutional debility; and is very frequently the consequence of masturbation. Primary debility and consecutive exhaustion, in these manifold conditions, are always attended by a weak or unusually flexed state of the joints; and whether appearing in childhood, or in later periods of life, the joints and ligaments most prominently betray these conditions. The more vigorously the joints and ligaments perform their offices, the more perfectly are the several vital functions performed. When the joints swell, or are puffed, in the advanced course of the severer cases of small-pox, or of scarlet fever; or at an advanced stage of puerperal phlebitis, or even in other forms of phlebitis, or in erysipelas, secondary inflammation and consecutive suppuration, in these parts may be considered to have either commenced or somewhat advanced. There are no external parts, which more certainly evince depression of organic nervous or vital power, or more frequently experience the injurious effects of infection or contamination of the blood — whether animal or external infec-

tion, or self-contamination by suppressed excretion or morbid absorption — than the joints, as I have shown and explained when treating of the SYMPATHETIC ASSOCIATIONS OF DISEASE (§§ 21, 72.).

51. Not only the large, but also the small joints are objects of attention in disease. The latter are often the seats of painful affections, especially in females after the menstrual epoch of life, or during far advanced age, these affections partaking more or less of a rheumatic or of a gouty character, or of both. They are generally dependent upon disorder of the digestive and biliary organs and impairment of the excreting functions of the skin and kidneys. The last joints of the fingers are often enlarged in phthisis, whilst their ultimate extremities are wasted, and the nails are uncated or bent over the wasted tips of the fingers. In most diseases of debility or exhaustion, and in febrile maladies, the motions of the joints, and especially the remarkably impaired power of sustaining the weight of parts superimposed when the limbs are extended in attempting to stand erect, evince the degree of vital depression, and the loss of muscular and nervous energy.

52. The extremities also beyond the larger *joints* become the seats of *emaciation*, or of *œdema* — of the *former* in protracted chronic diseases and in those just named, of the *latter* especially when the limbs are depending, or when the venous or lymphatic circulation is interrupted by pressure, or by vital exhaustion or other causes. When œdema or swelling of one or more extremities occurs from the pressure of internal tumours, or appears in the last stage of phthisis, it is an unfavourable sign; in the latter disease especially, it generally ushers in a fatal issue. It is a very prominent sign of inflammation of the lymphatics, or of the veins, or of both; and it sometimes occurs in artereitis. In phlegmasia alba dolens, the swelling is very great, with little or no pitting by pressure, the veins and lymphatics being generally obstructed, and the adipose and cellular tissues loaded with a semi-coagulated lymph. Œdematous swellings of the extremities are always unfavourable signs when they appear in the course of prolonged internal maladies, especially upon diseases of the heart, kidneys, lungs, liver, or spleen; or upon ovarian disease, or aneurism, or internal abscess, or tumour. If œdema affect one arm it is generally unfavourable, although no disease of the heart, lungs or pleura can be detected. Swelling of the arm is a very important sign of tumours, especially cancerous diseases of the mamma, as showing that the lymphatics, or even the veins, have become affected. Œdema of the lower extremities, when owing chiefly to debility, or to a depending position, or to both, or to the pressure of the gravid uterus, or of fæcal accumulations in the cæcum or sigmoid flexure of the colon, generally disappears after the removal of the cause.

53. The *nails* of the fingers and toes, and the *hair* are often affected by internal as well as external maladies. The *nails* frequently manifest cachectic states of the system. They become elongated and uncated, or bent over the wasted tips of the fingers in phthisis; often also blue in this malady and in other diseases of the lungs and air-passages, when the blood is not sufficiently changed by respiration, and in congestion of the heart or lungs. They, with the fingers, assume a still more livid hue towards the fatal termination of these diseases, and during the collapse of pestilential cholera. The nails and matrix, or secreting structure of the nails are altered, the former becoming thick, or brittle, dry, &c., in several chronic cutaneous affections, especially in psoriasis, lepra, pityriasis, &c., evincing an obstinate form of those affections. The nails partake, to some extent, of the alterations of the cuticle, in acute and chronic diseases attended by exfoliation of this tissue; the hair also becoming implicated.

54. In acute or febrile phthisis, in exanthematous and in continued fevers, the *hair* falls out, becomes thin, dry, weak and straight. This affection of the hair is not very marked in chronic phthisis, and it does not occur until the most advanced stages of, or in the course of convalescence from these fevers. The hair falls out more slowly in consequence of the syphilitic and mercurial poisons, of masturbation, of premature or excessive sexual indulgences, of mental exertion, and the depressing passions. It becomes prematurely *grey* from pityriasis, from sudden mental shocks, from the depressing emotions, from excesses of all kinds. Loss of the hair, premature greyness, and exuberance of the hair, are severally more or less hereditary in families. The loss, greyness, or want of lustre of the hair, depends upon defective nutrition or atrophy of the follicular bulbs of the hair. (See Art. HAIR.)

55. II. SYMPTOMS AND SIGNS FURNISHED BY THE SENSES AND NERVOUS SYSTEM OF ANIMAL LIFE. — The *signs* furnished by *the organs of sense*, are dependent on the states of the brain, although often more or less influenced by the organic nervous system. The intimate dependence of the senses upon the brain is evinced most remarkably by the *eyes*, and less so by the function of *hearing*. The sense of *smell* is influenced by the respiratory functions and states of the brain and respiratory passages, whilst the brain is often affected through the medium of this sense. *Taste* is very closely connected with the digestive and organic functions. The sense of *touch*, whilst depending on the brain, requires the media of transmission to the brain to be capable of conveying the impression which touch produces. In all cases, it is necessary to *perception* through the medium of any of the senses — 1st, that an impression be made on the sense; — 2nd, that the nerves of sense should be in a state capable of transmitting the impression to the brain; — and 3rd, that the brain should be able to perceive the impression which has thus been made. The impression made on the senses may fail in either of those quarters or channels. — (*a*). The impression may fail owing to the *organ* of sense not being in a state to receive it at all, or to receive it in a normal manner, — as the eye or ear from disorder or disease; or the organs of smell and of taste, from diseases of the respiratory and digestive organs, with which they are connected. — (*b*.) It may not be perceived from the circumstance of the nerves of sense not being capable of transmitting the impression to the brain, as in cases of atrophy, injury, wounds, &c., of these nerves, or of tumours, morbid deposits, &c., pressing upon them: — and, (*c*.), the impression may not be perceived, although received and transmitted, owing to the condition of the brain at the origins of these

nerves in the brain, or at the seat of conscious sensation. — (*d.*) While these are the requisites for the discharge of the functions of sense, diseases of other organs influence these functions, in one or other of these three quarters — by implicating or disordering either the organ of sense, or the nerves communicating with the brain, or the brain itself.

56. Disorders of the functions of sense are of importance according to the sources to which they may be traced. They are most serious or dangerous when they can be referred to the brain; much less so when they proceed from the nerves of sense or from the states of the organs of sense, and least so when they are sympathetic, or depend upon the digestive functions. Owing to diseases of one or more of these quarters or sources, the functions of sense may be suspended, destroyed, diminished, depraved, or exalted; these several conditions depending upon any one of these sources, or upon two or more of them. They may be abolished or suspended in fevers, apoplexy, palsy, &c.; they may be depraved or altered in nervous fevers, and in diseases of the respiratory and digestive organs; they may be diminished or impaired, in these and many other maladies, and they may be exalted early in fevers, in inflammations of the brain, spinal chord, or their membranes, and even in hysteria and hypochondriasis. It is so far favourable when the senses continue unaffected in acute diseases; and a return of their functions after a crisis in these diseases, or in conjunction with other early favourable symptoms, is a fortunate concurrence.

57. i. The Signs presented by the Eye are amongst the most important which are furnished by the senses. The volume, the position, the motions, the colour, the brightness and expression, the states of the several tissues, and the functions of the eyes demand a particular notice. The pathological changes of the organ are described in the article Eye, the sympathetic and symptomatic indications furnished by it are now only to be considered. — (*a.*) The *size* of the eye is changed chiefly in hyperæmia of the tissues of the organ, in congestions of the brain or of the heart or lungs, by impending suffocation; in apoplexy in phrenitis, in the paroxysms of epilepsy and convulsion, in delirium tremens, &c.; but the increased size is not great, the apparent increase being caused more by the prominence given to the organ by congestion or turgescence of parts posterior to it, than by the distension of its tissues. In these cases, the volume and prominence of the globe are rapidly or acutely increased; but they may be augmented in a much slower and more remarkable manner, in several chronic structural changes of the organ. (See Art. Eye, *pluries.*)

58 (*b.*) The eye may be *protruded* slightly by turgidity of the tissues behind it, giving it also an apparent increase of size; and more remarkably by tumours, by aneurisms, by exostosis or osteosarcoma, by disease of the periosteum, or of the lachrymal gland; by structural changes of the membranes, bones, &c., and by inflammation of the adipose tissue behind the eye. The position of the organ may be variously altered by these maladies. The eye may be directly protruded, or it may be forced, or turned to one side.—*Sinking* of the eye (§§ 8.), is caused by absorption of the adipose substance behind the globe, by diminished turgescence of the vessels, and partially by an atrophy or lessened fulness of the tissues and humours of the organ. Sinking of the eyes is generally equal as to both, as it depends upon constitutional causes, and, when very remarkable, it is always a sign of a severe or dangerous malady. Where only one eye is sunk, a local affection of the brain, or atrophy of the nerves of the eye, or paralysis of these nerves may be inferred.

59. (*c.*) The *motions* of the eye may be affected by paralysis, or spasm, or by debility, exhaustion, &c. Immobility and wrong direction of the globe, may arise either from paralysis or spasm, and are signs of disease of the brain or of its membranes, especially congestion, effusion of fluid, hæmorrhage, softening, or any of the alterations productive of apoplexy, palsy, coma, convulsions, &c. Immobility is observed chiefly in catalepsy, apoplexy, and profound coma, and indicates a severe or very dangerous state of the latter. A faulty direction of the eye-ball, when permanent, depends chiefly on paralysis of the muscles on the side opposite to that to which the eye is turned, and more rarely to contraction of the muscles of that side. Squinting is a sign of organic alteration of the membranes or substance of the brain; is most frequently seen in hydrocephalus, in convulsions, apoplexy, cerebral inflammations, palsies; and is a most unfavourable or fatal sign of these maladies, the exceptions to this issue being few. During crises, or when it is observed in cases of worms, or in the paroxysm of epilepsy or hysteria, it is not so dangerous as in the foregoing maladies. Congenital or acquired squinting — acquired from habit — has no semeiological import.

60. Distortions of the eyes, of a passing or temporary kind, are produced chiefly by spasms of the ocular muscles, and occur chiefly in convulsive affections, in the diseases just mentioned, and in several acute maladies. When they are observed on the invasion of acute diseases, especially in any of the exanthemata, as small-pox, a most severe or dangerous attack is then indicated. If they appear in an advanced stage of cerebral diseases, of exanthematous or continued fevers, or in low or putro-adynamic fevers, the prognosis is still more unfavourable, or even fatal.

61. (*d.*) The *colour* of the conjunctiva should not be overlooked: redness of this coat is a sign of congestion or inflammation, either of it, or of congestion or inflammation of the brain or its membranes. The redness is most frequently the result of irritation from mechanical causes, or of catarrhal inflammation. When it is produced by acute sthenic inflammation then the conjunctiva is also much swollen. In the asthenic states of conjunctivitis, and in scurvy, the colour is a dark red. In apoplexy, in cerebral fevers, and in typhus, the conjunctiva is generally more or less congested and red; and frequently also in cases of vascular determination to the brain, especially in the morning before leaving bed. *Ecchymoses* of the conjunctiva are sometimes also observed in these maladies, and after epileptic or other convulsive attacks, these changes of this coat indicating a severe or dangerous disease. If the injection or congestion of the conjunctiva present a dirty brownish, or livid hue, not only cerebral congestion, but also alteration of the blood may be inferred, and a most unfavourable or fatal prognosis may be formed, especially in putro-adynamic

fever, typhus, small-pox, scarlet fever and measles. Other changes in the eye connected with simple, gouty or rheumatic inflammation, and the several alterations of structure of this organ, are described in the article Eye.

62. (*e.*) The *form and size of the pupil* are much affected in cerebral diseases, and in other maladies, through the medium of the sympathetic nervous system. A *contracted* pupil is observed in active vascular determination to the brain, in inflammation of this organ or of its membranes, in the early stage of irritation or scrofulous disease of the brain, before passing into effusion, in retinitis, and in poisoning by opium. When it occurs in apoplexy, or when one pupil is contracted whilst the other is dilated, either in apoplexy, palsy, or epilepsy, an unfavourable prognosis may be formed. A *dilated* pupil occurs in an advanced stage of hydrocephalus, in coma, and in all diseases of the brain attended by effusion or pressure, as apoplexy, the last stages of phrenitis, and meningitis. It may occur also after epilepsy, convulsions and hysterical fits; and it may be produced by some narcotic poisons. Its connection with amaurosis and cataract should also be recollected. Dilatation of the pupil is observed in cases of intestinal worms, and often in scrofula, the early stage of phthisis, and in several chronic abdominal affections, especially in children. When it follows rapidly on a contracted pupil, during cerebral affections, effusion or organic alterations may be inferred, the latter especially if any difference in the state of both pupils be remarked.

63. The *motions* of the *iris* should always be noticed in connection with the size of the pupil. The iris may be unaffected by light, owing either to spasm or paralysis; this want of motion being most frequently remarked in the cerebral maladies already mentioned, and in typhoid and low fevers. In these, as well as in other maladies, of a severe or dangerous nature, this is a most unfavourable sign. Increased sensibility of the iris, with quick dilatation or contraction, is observed chiefly in hysterical and irritable or sensitive states of the frame; and in the early periods of exanthematous or other fevers. It is also remarkable in diseases of debility, or in cases of vital depression, when the functions of the brain are unimpaired.

64. (*f.*) The *lustre* of the eye depends chiefly on the state of the brain. It is increased in active determination of blood to, and in inflammations of, the brain or its membranes, until effusion, exhaustion or coma supervene. Increased lustre is sometimes observed in apoplexy; it precedes and accompanies the delirium of fevers; and attends several states of insanity. The lustre of the eye is impaired on the invasion of most infectious maladies; in congestive affections of the heart, lungs or brain, and in severe diseases of the abdominal organs. The lack of lustre is further increased in the last stages of acute diseases, especially when the blood is contaminated, as in malignant or pestilential maladies; and is always a very unfavourable sign. It is often a fatal indication in inflammations of abdominal organs, and in these it evinces the occurrence of gangrene or fatal sinking. A glazed appearance of the eyes generally precedes dissolution.

65. (*g.*) The *expression* or *look* of the eye, or the impression made by the eyes of the patient on the observer, is generally either that which is natural or usual, or that of anxiety, of terror, fright or despair, or of wildness or madness. The expression of the eye generally harmonizes with that of the countenance. The *natural look* of a patient's eye is always a favourable circumstance in both acute and chronic diseases. A *timid* or *mild expression* is observed on the invasion of acute diseases, and before vascular reaction is developed, and towards the termination of dangerous chronic maladies. It is also seen in hysteria, in disorders caused by self-pollution, and hypochondriasis. A *timid, furtive, downcast*, or *unsteady* look is common in the disorders of the mind. An *anxious expression* is observed in diseases of the heart, and of the respiratory passages, when the respiratory efforts are difficult, and in inflammations of the stomach, bowels or liver. A look of *fright* or *despair* occurs in alarming cases of hæmorrhage, in violent colic or ileus, in strangulation of the bowels, in pestilential cholera, sometimes in acute inflammations of the digestive canal, and in accidental poisoning. It is always an unfavourable, and frequently a fatal sign. A *wild, terrified* or maddened expression characterises the paroxysm of rabidity, the accession of delirium and mania, delirium tremens, and phrenitis or meningitis.

66. (*h.*) The *function of vision* is variously affected in disease, either with, or without, *increased* or *diminished sensibility of the eye* to light. *Increased sensibility* to light (*Photophobia*) is observed in many diseases, — 1st, in diseases of the eye, especially in inflammations of the internal tissues, and in scrofulous, gouty and rheumatic affections of the organ; — 2nd, in diseases, in which affections of the eye become prominent phenomena, as small-pox, measles, catarrhs, &c.; — 3rd, in affections of the brain or of its membranes, especially in inflammations or irritations of, and vascular determinations to, this organ, whether primary or associated with febrile or other maladies. Photophobia is generally observed during the early stages, and progress of these, and before effusion or other organic changes consequent upon inflammatory action, or irritation have supervened. It also occurs in delirium, in mania and several states of insanity; — and 4th, in various diseases, in which the nervous systems generally, both organic and animal, evince increased susceptibility and sensibility, as hysteria, hypochondriasis, rabies, and during recovery from many acute maladies. *Impaired sensibility* of the eye to light often occurs in far advanced stages of the diseases, in the earlier periods of which increased sensibility is observed. The *sensibility* of the eye to light, whether increased or diminished, should not be confounded with increase or loss of the power of vision; for vision may be very remarkably impaired, when the sensibility to light is most acute, and the reverse is as frequently observed.

67. (*i.*) *Diminution or loss of vision* may arise from a variety of pathological states. — 1st, from changes in the tissues and humours of the eye itself; — 2nd, from disease of the brain, of its membranes, or of the optic nerves, or of changes implicating either these nerves or the ophthalmic branches of the fifth pair of nerves; — and 3rd, from sympathy with disease of any of the abdominal organs: from intestinal worms; from hysterical hypochondriacal and of the nervous affections;

from faintings, and from general or local debility or exhaustion (see Arts. Eye and Amaurosis). When loss, or even diminution of sight occurs during delirium, or in the course of fevers, and in affections of the brain, the supervention of coma, or of apoplexy or palsy, or of both, may be expected.

68. (*k.*) *Morbid* or *altered vision* presents various forms and phases. — *Near* or *far sight* depends on the different degrees of convexity of the cornea, and on the states of the anterior humours or parts of the eye-ball. Near sight (*Myopia*) is often congenital and continues through life, or nearly so. It may, however, be acquired from the constant or frequent use of the eyes at near objects, or at the same near focus. Far sight (*Presbyopia*) may occur from habitually directing the eyes to distant objects, and is common in sailors. It is still more common in advanced age. It is owing chiefly to diminished convexity of the cornea. *Interrupted* and *half vision* occurs either from a partial paralysis of the retina, which is sometimes temporary and sympathetic, or from a more permanent change in the humours or nerves of the eye. It is generally symptomatic of disorder of the digestive functions when it is not continued; but when it is constant or increases, it is caused by a change in the optic nerve or optic thalamus.

69. *Double vision* generally proceeds from disease of the brain or membranes, from effusion of fluid within the cranium, or from alterations implicating the medulla oblongata or base of the brain. It is an unfavourable sign whenever cerebral disease is indicated, especially phrenitis, apoplexy, palsy, epilepsy, &c. It may usher in a dangerous attack of apoplexy or palsy, or precede amaurosis, or it may follow the severer paroxysms of epilepsy or convulsions. It sometimes occurs on metastasis of rheumatism or gout to the brain; and it occasionally supervenes upon, or attends disease, especially inflammation of the spinal chord or its membranes, and it is then a most dangerous sign, inasmuch as it evinces the extension of disease to the base of the brain. Double vision may accompany intoxication, intestinal worms and disorders of the digestive organs, fæcal accumulations, hysteria, &c. But it is then associated with symptoms which indicate its nature, and is commonly temporary or soon removed.

70. *Vision* may be deformed, — objects being seen in inverted, crooked, disfigured, or distorted forms. This state of vision occurs chiefly in cases of chronic organic diseases of the brain, membranes, or bones of the cranium. Objects may also appear brighter or darker than they really are, or different colours, or certain colours may not be distinguished. A *brighter* or redder appearance of objects than natural sometimes accompanies irritation or inflammation of the brain or its membranes. A *dim* or *dark* state of vision may proceed from debility of the retina, or from slight turbidity of the humours, or congestion of the posterior structures of the eyes. An inability to distinguish colours, or to perceive certain colours, indicates congestion, or alteration of the intimate structure, of the retina. *Scintillations*, sparks, lights, or little fiery balls (*Photopsia*), occur in congestions, hyperæmia, and inflammations of the brain or membranes, and they sometimes precede epistaxis, apoplexy, palsy, amaurosis, epilepsy, &c.; but they may also proceed from irritation of the retina and optic nerve, and from congestion or inflammation of the more internal tissues of the eye.

71. *Dark points*, figures or nets, or reticulated spots (*Muscæ volitantes*), before the eyes, sometimes proceed from congestion, irritation, or inflammation of the retina and adjoining parts, but more frequently from slight capillary congestion of the interior structures, especially the capsules of the humours, or turbidity of the humours, or varicose states of the extreme or lymphatic vessels. These appearances, as well as others of a similar kind, may sometimes depend upon congestions within the cranium. The states of the organ from which they chiefly proceed are generally sympathetic of disorders of the digestive organs, and are often associated with chronic cutaneous eruptions. They are also symptomatic of intestinal worms, of hypochondriasis, and hysteria. They are most frequently experienced by persons who have strained or over-exerted their sight on small or near objects. These disorders of vision may be more or less manifest for many years, — for thirty or forty years, — according to my experience, without much disorder of the general health, when they are not made the subjects of local treatment, by speciality doctors or surgeons, to whom, owing to the alarm of patients, they have often furnished rich harvests.

72. (*l.*) *The seeing of objects which have no existence—Illusions of sight*—are common in delirium, especially the delirium of fever, in states of fright or terror, in morbid states of the imagination, in delirium tremens, in states of intoxication, in the several states of acute or chronic insanity, in meningitis, and in rabies. It occurs chiefly from irritation or congestion of the cineritious portions of the brain, and is common in typhoid, low, continued, and exanthematous fevers, and in the last moments of sinking vitality, in acute and chronic maladies.

73. (*m.*) The functions of the *lachrymal glands* are often disordered in disease. The secretion of tears is generally impeded in fevers, especially during the early stages, when all the secretions are scanty; the dryness of the conjunctiva in these diseases, as well as in exanthematous fevers, favouring the occurrence of inflammation of this membrane. Increased secretion of tears may be either apparent only or real. It is often the former, when the carunculæ lacrymales are red, swollen, or partially obstructed by inflammation, catarrh, &c. It is the latter in hysteria, hypochondriasis, in low and mentally depressed states of disease, in nervous fevers, and in the depressing mental emotions. An increased flow of tears is often most beneficial in severe mental shocks, and on occasions of mental distress: it is, however, frequently produced at pleasure, or in paroxysms of temper, by females.

74. ii. The Sense of Hearing furnishes signs, which have reference,—1st, to diseases of the organ itself; 2nd, to diseases of the brain, with which this sense holds intimate relations; and 3rd, to diseases of more distant and less obviously related organs. The *first* of these have been treated of in the article Ear, and *diminution or loss of hearing*, from diseases of the *organ*, or of the *brain*, or of more *distant parts*, has been fully considered in the article Hearing. There

remains, therefore, but little further to say respecting the signs of disease furnished by this sense. *Noises* in the ears, and *ear-ache*, are also severally symptoms of disease, either of the ear itself, or of parts in the vicinity, as of the throat or pharynx, or of distant parts, or of the system generally, especially continued fevers.—*a*. The *former* often precede the accession of delirium, and attend and aggravate delirium tremens. Noises in the ears also accompany anæmia, especially that consequent upon protracted rheumatism occurring in far advanced life; and they frequently attend diseases of the uterine organs, or large losses of blood either by hæmorrhage or by excessive blood-letting. In plethoric persons, they sometimes usher in an attack of apoplexy, or of epistaxis; and they should be viewed as unfavourable signs. When they are experienced in very aged persons, especially in females, who pass sedentary lives, without exercise in the open air, although not indicating danger, they resist all means of cure, if exercise in the open air be not regularly and perseveringly taken. (See Art. Ear, *Nervous affections of*.)

75. *b*. *Earache* is an unfavourable symptom in continued and exanthematous fevers, especially in scarlet-fever and small-pox. In these, as well as in other constitutional maladies, and even in secondary syphilis, it indicates the supervention of a local inflammatory complication, generally extending from the throat, along the Eustachian tube to the ear, and frequently either destroying the organ, or, after effecting this, extending to the membranes and substance of the brain, as I have shown to occur on many occasions, in connection with these and other maladies (see Art. Brain, §§ 146. *et seq*.). The importance of giving due attention to earache, and other affections of the ear, with reference to their pathological and semeiological relations, is more fully shown in the articles on Earache, and on *Inflammation of the* Ear.

76. iv. The Sense of Smell has intimate relations with the brain and respiratory functions.—*A*. *Acuteness of smell* (hyperosmia) is often present at the commencement of irritation or inflammation of the brain or its membranes, or of nervous, typhoid and exanthematous fevers, and in hypochondriasis, hysteria, uterine affections, and often in epilepsy. It sometimes precedes the accession of mania or delirium.—*B*. *Want of smell* (anosmia) is occasioned by affections of the nasal membrane, in catarrhs, influenza, inflammations, &c.; and by chronic diseases of the brain, or of the membranes, or of the bones of the cranium; or by secondary syphilis, or by the progress of low or exanthematous fevers.—*C*. *Perversion* of this sense, or smells which are different from those perceived by other persons, or which are peculiar, or unusual, sometimes precede an attack of apoplexy or of epistaxis, or of paralysis. It sometimes attends disorders of the digestive organs, hypochondriasis, hysteria, uterine diseases, secondary syphilis, and organic diseases of the brain and cranial bones.

77. *D*. *The secretions* of the nose are affected in catarrh, influenza, in scrofulous affections, in continued and exanthematous fevers, in syphilis, in worms, and in various disorders of the respiratory and digestive organs.—*a*. *Itching* of the nostrils is a sign of the presence of intestinal worms, especially of the small-thread worm; and in females, of irritation of the sexual organs, often connected with masturbation. It occasionally precedes epistaxis, and in aged persons it sometimes is a prelude of dangerous cerebral disease.—*b*. *Hæmorrhage* from the nose (*epistaxis*) occurs under circumstances which have been fully described in the article Hæmorrhage (§§ 65. *et seq*.). It is often a critical discharge in febrile, inflammatory and congestive diseases, especially in congestions of the heart, lungs or brain, and in active determinations of blood to the last named organ. The occurrence of it may avert an attack of apoplexy or of palsy, when not injudiciously suppressed, especially at advanced periods of life. Passive epistaxis, the vessels being defective in tone, and the blood deficient in crasis, or poor, or contaminated, as often observed in cachectic habits, or in putro-adynamic states of fever, in scurvy, purpura, &c., is often attended by much risk, especially when these conditions of the blood and of vital power are prominently marked, and decided measures the most calculated to arrest the discharge are then required. (See Art. Hæmorrhage, §§ 15. 16. 17. *et seq*.)

78. v. The Sense of Taste is often affected in connection with disorder of the sense of smell. It is either acute, impaired, lost or vitiated in disease.—*a*. It is rarely more *acute* than natural. Acuteness of taste is most frequently observed in hysteria, hypochondriasis, in nervous affections, and occasionally in nervous fevers.—*b*. Taste is *impaired* or *lost* in catarrhs, catarrhal fevers, influenza, in acute or inflammatory indigestion, in chronic gastritis, or gastro-enteritis; in a loaded or saburral state of the digestive mucous surface. In congestive or inflammatory states of the brain, and in low, continued and exanthematous fevers. When taste is restored early during convalescence from these maladies, a favourable issue may be expected; when it does not return during advanced convalescence from apoplexy, or other diseases of the brain, or from gastric or cerebral fevers, a renewed attack or a relapse may be dreaded, especially if the sense of smell also does not return.

79. *c*. A *vitiated taste* is very common in all disorders of the digestive organs; frequently in nervous disorders, and often in affections of the respiratory passages.—*d*. The taste may be *insipid* in catarrhal affections, in periodic fevers, in mucous fevers, and in cases of intestinal worms.—*e*. It may be *bitter*, in biliary disorders, in bilious fevers, in jaundice, and in chronic and structural diseases of the liver, spleen or pancreas, especially if it continue notwithstanding the ingestion of wholesome food.—*f*. *An acid taste* is experienced during heart-burn, indigestion, and disorders of the digestive organs generally. It is often caused by gout, or rheumatism, or calculous affections, by flatulence, or by eructations from the stomach. *g*. A *salt* or a *sweetish-salt taste* is occasioned by the presence of small quantities of blood in the mouth, and by the expectoration of matters from the lungs containing either blood or purulent matter; and is thus present even in the early stages of pulmonary disease, especially phthisis.—*h*. A *putrid* or *foul state* occurs in gangrene of the lungs, and in syphilitic and scorbutic affections of the nose, gums or throat. It is caused also by caries of the teeth or gums, by the expectoration of puriform

matters, and by the discharge of abscesses by the mouth. It is an unfavourable sign, in pulmonary, constitutional and cachectic diseases, and in chronic maladies, especially when there is much debility or emaciation. It may occur in gangrene of any part of the digestive canal, and in adynamic dysentery, and then it should be viewed as a fatal indication.—*i.* A *metallic taste* is caused by the constitutional operation of mercury, and it often precedes the accession of salivation, or mercurial affection of the gums. It is also sometimes produced by other metallic poisons; and, in rare instances, it is experienced in agues and in chronic abdominal disorders. The states of the *tongue* are various, with or without the above alterations of taste, but they will be noticed in the sequel (§§ 101. *et seq.*).

80. vi. The Sense of Touch may be more or less altered, either in one limb or extremity, or in two or more.—(*a.*) *Acuteness* of the sense of touch is observed in irritation or inflammation of the brain, spinal chord, or their membranes. It sometimes precedes mania, delirium and apoplexy, and often attends hysteria, rheumatism, gout and hypochondriasis.—(*b.*) *Diminution* of the sense of touch, in various degrees, is observed in organic diseases of the brain, spinal chord, or their membranes, and especially when these changes are consequent upon inflammatory action, effusion or softening, or tumours. When loss of touch proceeds from these pathological states, the result is generally unfavourable. It may occur in hysteria, hypochondriasis, in chronic affections of the skin, epilepsy, delirium, syncope, &c., and then a less unfavourable opinion may be entertained. It may precede a crisis in fevers. But no dependence should be placed upon it as a sign in these cases.—*c.* *Perversion* of this sense occurs in chronic changes in the brain, spinal chord, or their membranes, in nervous affections, and in misplaced gout affecting the brain, or its membranes. In these cases of perversion, the sensation of some body intervening between the points of the fingers and the objects touched is generally experienced.

81. vii. The Signs furnished by Sensation or Sensibility, depend, as those evinced by the senses, either upon the state of the affected part, upon the channels transmitting sensation, or upon the medulla oblongata and parts in the centre or base of the brain, which are more especially connected with the perception of sensation, or with conscious sensation. *Sensation*, whether *animal* or *organic*, is either exalted, impaired, or perverted, or suspended in disease. It may, moreover, be variously exalted and perverted in the same case, this conjoined alteration giving rise to a variety of feelings which have been recognised by distinctive appellations. These may severally proceed from the same pathological conditions as have been mentioned in connection with alterations of the sense of touch.—*a.* *Exaltation* of sensibility is observed in irritation and inflammation of the spinal membranes, medulla oblongata and chord, in similar affections of the cineritious structure of the brain, in hysteria, hypochondriasis, rabies, &c.

82. *b.* *Diminished* or *suspended*, or *lost sensation* occurs in apoplectic, convulsive, paralytic, epileptic and catalyptic seizures, during syncope, and in all changes of the brain, medulla oblongata, spinal chord and membranes, occasioning temporary or more permanent loss of consciousness, or anæsthesia. It may accompany, in its less manifest states, continued fevers; and in its more extreme grades, it may follow delirium in the form of *sopor* or *coma*, in these and all other fevers. In all these maladies it is an unfavourable, and in many a most dangerous sign. Impaired or lost sensibility to the common wants of the economy, or to the usual or natural irritants or stimulants, or the loss of sensibility in parts not liable to the deprivation of it, is always a dangerous indication.

83. *c.* *Perverted sensibility*, or depraved sensation, is more generally associated with exaltation, than with diminution, of sensation. Whilst exalted and impaired sensation should be referred chiefly to the cerebro-spinal nervous system — to *animal sensibility*, depraved sensation, as respects its chief manifestations, depends upon *organic sensibility* — upon the state of the organic or ganglial nervous system. Perverted sensations referrible chiefly to animal sensibility, are itching, formication, stinging, tingling, pricking, tickling, burning, &c. They are felt in the integuments, and in the extremities — in the latter, during organic affections of the brain, spinal chord, and their membranes; and previously to, or upon recovery from, an attack of apoplexy, palsy, epilepsy, convulsions, gout, &c.; — in the former, in exanthematous fevers, either previously to, or during the appearance of the eruption, and in numerous acute and chronic cutaneous diseases. Tickling or titillation, or a sensation intermediate between this and itching, is often experienced in the soles of the feet or palms of the hands, and sometimes in other places, without any disease being either present or expected. The former of these situations may, however, be artificially tickled so as to induce violent convulsions; and, if this cause be persisted in, the result may even be fatal. Spontaneous sensations of itching and tickling may also become so distressing as to occasion convulsions, delirium, or even mania, in hysterical and nervous persons, but this is very rarely observed. A sense of burning in the soles of the feet and palms of the hands is frequent in the gouty and rheumatic diathesis, in hectic and in morbid states of the circulating fluids.

84. *B.* *Perverted sensations*, which are referrible chiefly to the organic nervous system — or *perverted organic sensibility* — vary very remarkably, from a sense of uneasiness and restlessness, to that of distress, anxiety, and acute pain.—(*a.*) *Uneasiness* or *discomfort* occurs in the invasion of most acute maladies, and more especially of those produced by infection; but it also is observed after the suppression of any of the secretions and excretions, and on the appearance of any eruptive disorder. It also attends most chronic complaints, especially hysteria and hypochondriasis. *Restlessness* may be considered as a higher degree of discomfort, and is generally present in the circumstances just stated, or it follows uneasiness, during the accession of disease. A most distressing state of restlessness, or that attended by more or less anxiety, is observed at a far advanced stage of chronic and often also of acute diseases. Restlessness at the commencement or at an early period of acute disease is always an indication of a most severe or dangerous attack. If it appear

in the course of febrile complaints, it is often occasioned by the accession of some important complication, especially in children, as inflammation of the brain, spinal chord or membranes, or carditis or pericarditis. It may, however, usher in a critical discharge; but if it continue, or appear after a crisis, in acute maladies, or at a far advanced period of either acute or chronic diseases in connexion with vital depression or exhaustion, or with frequent or difficult or anxious respiration, it is always a very unfavourable or fatal sign — usually fatal when it is referred to a state of internal feeling of distress or anxiety.

85. (*b.*) Discomfort may proceed to restlessness, thence to distress, and thence to a feeling of *anxiety*, which is merely a more extreme sensation of distress. These grades of morbid organic sensibility vary somewhat in character and severity, according to the region or organ chiefly affected. The distress or anxiety attending asthma, pneumonia, effusion into the pleural cavities — *anxietas pulmonalis* — is different, and distinguished by the patient as different, from that which proceeds from disease of the heart, pericardium and large vessels — *anxietas cardiaca* — and from that which is occasioned by acute disease of the stomach, liver, diaphragm, or by the ingestion of acrid poisons, or any of the more dangerous maladies of the abdominal viscera — *anxietas præcordialis.* Always keeping in recollection the differences between mental and bodily distress or anxiety, the latter should be referred especially to the morbid impression, or suffering, experienced by the organic nerves of the affected organ. This suffering may either exist in one of the organs just noticed, or be extended to several of them, or it may also implicate the nervous system of animal life, and occasion the *anxietas nervosa*, as in hysteria, hypochondriasis, rabies, tetanus, nervous fevers, &c. A feeling of *anxiety, distress,* or *suffering*, may accompany the cold stage of periodic fevers, or the invasion of malignant or pestilential maladies, or it may accompany the accession of a crisis. In these cases, although a most severe attack may be expected, inasmuch as this sign is an indication of the serious morbid impression made upon the organic nervous system, one of the prime factors of life, yet the danger is not so great as in those cases, in which this feeling supervenes in a far advanced stage of the diseases above mentioned. When it thus occurs in this stage, when it follows closely upon acute inflammation, or when it is of long duration, the danger is very great, and even extreme in pestilential maladies — *anxietas moribundorum.*

86. (*c.*) *A feeling of cold*, as already shown (§ 19.), may exist independently of any depression, and sometimes even in connection with an increase of the animal temperature. It may be attended by shiverings, shudderings, rigors or even horrors, according to the grade or intensity of this feeling. The severity of this sensation is generally an indication of the severity of the consecutive attack when it ushers in an acute disease — either inflammatory or febrile; and it is no less an indication of danger when it occurs in the advanced course of inflammations, of eruptive fevers, and even of chronic visceral disease. Rigors are often the forerunners of dissolution when they occur in diseases, in which debility or exhaustion is very remarkable (see above, §§ 20. *et seq.*). An internal feeling of cold, if experienced on the accession of disease, indicates a very severe and dangerous attack; if felt at a far advanced stage, it proceeds from fatal sinking.

87. (*d.*) *An internal sensation of unusual heat* is frequent in acute or inflammatory diseases, and it may be present when the surface is actually cooler than natural. The feeling of heat may depend upon states of internal or central parts which do not reach the periphery even of the trunk; and it, as well as the feeling of cold, is to be referred chiefly to the changes in the organ or part in which the sensation is felt, the organic nervous system participating in these changes in an especial manner, inasmuch as it is instrumental in the performance of the calorific process. A sensation of heat, or even of burning heat, may be concentrated in internal or central parts, may accompany either open or latent inflammatory attacks, and may exist, especially in the latter, although the external surface or the extremities be cool or even cold. Local feelings of heat are indications of irritation and local vascular determinations of blood, or of inflammation, or of approaching hæmorrhages. A general feeling of heat attends the more sthenic forms of fever, both periodic and continued, especially in the stage of vascular excitement. A local sensation of heat is much more dangerous in these fevers than a general feeling of heat, and when it is experienced in these diseases it should be viewed either as the precursor of a crisis by hæmorrhage, or as an indication of the supervention of a prominent affection or complication. If the cessation of internal heat be attended by free secretion or excretion, the prognosis is favourable; but if it occur suddenly, or is followed by a feeling of cold, the prognosis is bad. The sensation of heat may change its seat, especially in nervous fevers, influenza, hysteria, hypochondriasis, and diseases of the abdominal viscera; but the amount of danger in these complaints depends upon the concomitant symptoms and signs; and chiefly upon the other conditions of the surface, with which the sensation of heat or of cold is generally associated (see §§ 22. *et seq.*).

87. (*e.*) Feelings of *muscular fatigue*, of *general malaise*, or of *exhaustion*, or of *vital depression*, or of *sinking*, are chiefly modified grades of that depression of vital power accompanying either the invasion of acute diseases, or the debility consequent upon great excitement. When these feelings are very remarkable on the invasion of acute maladies, they augur a very dangerous attack; and when they become extreme at a far advanced period they are then attended by great danger, and they require the administration of very active restoratives, appropriately to the circumstances of the case. (See Arts. Debility and Disease (§ 67.).

88. C. Pain is a most important symptom, as indicating the seat, the nature, and even the probable result, of disease. It is a warning furnished by nature to convey this information; it both puts the patient on his guard to remove the cause of suffering, and disposes him to use the means for this purpose. It further tends to rouse the conservative influence of life — to excite the vital resistance — against the extension of disease,

to prevent dangerous or fatal sinking, and to bring about a salutary reaction. In order, however, that pain should have these salutary effects, it should not be allowed to be excessive or intense for a prolonged period, or without having recourse to means to assuage it; the expression of it, when excessive, ought not to be suppressed; and the effect of its continuance, as well as the several phenomena which accompany it, should be closely observed and carefully compared and estimated. In our investigations into the nature and seat of pain, there are several things to be ascertained, especially its *duration* and mode of *accession*, its exact *seat* and *relations*, its *character* and *severity*, and the influence produced upon it by different degrees of *pressure*, *percussion* and *temperature*.

89. *a*. *Pain* may be either *dull*, *obtuse*, or *heavy*, or *aching*, in connection with congestions and chronic inflammations, or with acute or chronic inflammations of parenchymatous organs, and mucous membranes, in cases of effusion into internal cavities, or of internal tumour, and sometimes in the congestions and vascular determinations preceding hæmorrhages.

90. *b*. A *gnawing* or *lacerating pain* generally accompanies rheumatism, gout, cancerous disease, &c. A *perforating* or *boring pain* is felt chiefly in diseases of the periosteum and bones, in secondary or tertiary syphilis, in scurvy, especially at night, in the long bones and joints. A *burning pain* attends gout, severe or intense inflammation of the integuments, erysipelas, carbuncles. A *pungent* or *tensive pain*, often with more or less of a sensation of burning, is experienced in acute inflammations of serous membranes; and in its most violent or stabbing form, in inflammation of fibrous, or sero-fibrous tissues, and in those affections of the nerves, which have usually been termed neuralgic, and which proceed either from inflammation of the sheath or neurilemma, or from irritation at or near the origin of the nerve. This kind of pain, also, especially when occurring at short intervals, and of brief duration, and characterised by violent dartings, accompanies the passing of gall stones, or of calculi along the ureters. A *cutting* or *darting pain* also attends cancer, and inflammation of nerves, in which latter it is often accompanied with a sense of numbness in the parts distant from the seat of pain, and is often, in this as well as in the other maladies just mentioned, characterised by a feeling of heat or burning.

91. *c*. A *pulsating pain* indicates extreme congestion of a parenchymatous organ, or the passage of inflammation into suppuration — commonly this latter when it is attended by horripilations, chills, or rigors (§§ 19.). When this pain is preceded by a feeling of tension, the existence of abscess, or of effusion into a shut cavity may be inferred. A *pricking*, *stinging*, or *tickling pain*, may accompany acute eruptions on the skin, gout, organic diseases of the brain, spinal chord, or their membranes, especially when these pains are felt in the extremities, and are attended, or are interrupted, by a feeling of numbness (§§ 41.), also hysteria, and hypochondriasis. A *violent twisting*, *spasmodic*, or *griping pain* accompanies dysentery, ileus, gastralgia, enteralgia, strangulated hernia, and obstructions in the bowels. A *forcing*, *acute pain* often also attends these maladies, the passage of concretions along canals, and diseases of the uterus and ovaria.

92. *d*. *The seat and duration of pain* suggest interesting considerations. The *seat*, however, should not always be received as a correct indication of the seat or origin of the disease: for, even in inflammations, the pain may be referred to parts at a distance from the seat of disease: thus, in pleuritis, the pain may be felt in the iliac regions, or below the false ribs; and, when a limited portion of the spinal chord or membranes is influenced, the pain may be referred to the distant extremities of nerves having relations with the seat of disease. This topic, is however, more fully illustrated in the article Sympathy.

93. The *duration* or continuance of pain is most various. It may be *transient*, *wandering*, *intermittent*, *remittent*, or *permanent*. *Transient pains* occur in hysteria, in gout, rheumatism, hypochondriasis, in catarrhal fevers and influenza, from irritation of the digestive organs, from accumulations of bile in the ducts or gall-bladder, and from irritation of the nervous centres of animal life. *Intermittence* or *remittence* of pain shows its seat in the nervous system, especially of animal life, and occurs chiefly in those diseases, in which this system in some part of its ramifications is more or less implicated, as in neuralgia, periodic fevers, rheumatism, gout, hysteria, &c. *Continued* or fixed pain indicates the more or less permanent nature of the malady, as inflammation, disorganization, rheumatism, syphilis. *Wandering pains* occur during the accession of acute or febrile diseases, in hysteria, hypochondriasis, syphilis, rheumatism, atonic gout, and in functional disorders of the digestive organs, especially h e liver and stomach.

94. *e*. *Pressure* and *percussion* produce certain effects on pain which are extremely important in diagnosis. *Tenderness*, or incapability of enduring pressure, or increase of pain on pressure, is a sign of inflammation or of organic change. But in nervous, hysterical and hypochondriacal persons, the tenderness may not be connected with increase of pain on pressure — may be merely a morbid, superficial sensation, or an intolerance of touch; for, when pressure is made, when the patient's attention is distracted, or firmly or forcibly, the pain is either not increased or is diminished, showing the true nervous character of the tenderness or pain in these. *Diminution* of pain on pressure characterises colic, chronic rheumatism, and nervous pains or pure neuralgia, when not occasioned by inflammation of the nerve or its sheath. *Increased pain* on pressure attends inflammation, organic changes, the results of, or the attendants of inflammation, and vascular congestion. Increased or continued pain, the skin being hot or dry, and the pulse hard, or rapid, is a sign of progressive inflammatory action; and if the pain become pulsating with chills, heats and sweats; the sweats not diminishing the pain or changing its pulsating character, suppuration may be inferred. *Prolonged pain*, with more or less tenderness on pressure, indicates organic change, especially if emaciation advances, and if the secretions or excretions be disordered. A *decrease* of pain after the secretions and excretions become free or augmented is always a favourable sign. A *cessation* of pain coinciding with remission of fever and increase of the natural discharges

is also a favourable symptom; but a sudden cessation, without abatement of the other symptoms, or with the appearance of others which are unfavourable, indicates the occurrence of gangrene, or of rapid vital sinking. *Pain* or *spasm*, or the association of both, in parts which are paralysed either as to motion or sensation, is an indication of inflammatory action, or of inflammatory softening in or near those parts of the nervous centres, with which the nerves of the affected parts have intimate relations. Severe pains or spasms in a different extremity or part from that which is paralysed, indicate the presence or extension of inflammatory action to those parts of the nervous centres connected with the origins of the nerves of the pained extremity. (See Arts. Headache, Irritation, Neuralgia, Paralysis, Spasm, &c.)

95. ix. The Mental Manifestations furnish numerous signs, in respect both of their individual conditions and morbid associations, and of their connections with acute and chronic physical disease. But these have been noticed, as far as my limits admit, when treating of Delirium, Coma, Sleeping and Sleeplessness, and of the different grades and forms of Insanity, in which latter especially, as well as in the other articles, I believe these subjects have been fully discussed.

96. III. The Symptoms and Signs of the digestive Functions and Organs.—These functions and organs are essentially vital, and are under the dominion of the organic nervous system — the primary or chief factor of life — excepting at the entrance to, and outlet from these organs; and to these situations, accessory influences are imparted from the cerebro-spinal or animal nervous system. The states and disorders of these functions and organs, from the entrance to them by the mouth to the outlet by the anus, are intimately connected with the conditions of the organic nervous system; whilst this entrance and this outlet are controlled by the cerebro-spinal nervous influence. Thus the functions of the several digestive organs are manifestations of the conditions of organic nervous power, and the functions of these portals are indications of states of cerebro-spinal influence. The symptoms and signs furnished by the digestive functions and organs, comprise those evinced by the *teeth* and *gums*, by the *tongue* and *throat*, by *deglutition*, by the *appetite for food* or *drink*; by the functions of *digestion*, by *fæcation* and *defæcation*, and by the *abdominal regions*.

97. *A.* The Mouth *&c.*—(*a*). *The Teeth* are perfect and enduring in persons of sound constitution, their soundness often continuing to advanced age. Their early decay indicates either constitutional vice, or impaired constitutional power, or prolonged disorder of the digestive functions. The teeth are variously affected by acute and chronic maladies.—*Chattering* of the teeth occurs in the cold stage of fevers and invasion of acute diseases, and indicates a severe form of the supervening malady. It is also observed in hysteria, but in rare instances; and in dangerous shocks of the nervous system. It is most remarkable in the cold stage of agues. *Grinding* of the teeth during sleep, is common in children, and is a sign either of intestinal worms or of cerebral disease. If it occur in children in connection with brightness of the eyes, contracted pupils, flushing of the cheeks, or startings in sleep, then convulsions, cerebral meningitis, scrofulous softening of the brain, or other changes may be apprehended. In aged persons it sometimes precedes an attack of apoplexy or palsy. If it occur in continued or in exanthematous fevers, it renders the prognosis more unfavourable, as evincing a serious cerebral complication. It may, however, take place in irritable persons and children, without any serious disorder, especially during dentition in children.

98. The teeth are often covered with a greyish mucus in catarrhal fevers, in gastric disorders, and in inflammations of the digestive and respiratory organs. They are more copiously covered by mucus or sordes of a dark or brown colour, often extending to the lips and gums, in low, adynamic, or putro-adynamic fevers; the quantity and darkness of the colour evincing the amount of danger. The accumulation of tartar or cretaceous matter around the teeth, at the margins of the gums, shows a disposition to calculous, gravelly, or gouty affections.

99. The teeth sometimes become inordinately sensitive in nervous disorders, in disorders of the digestive organs, and in acidity of the stomach. They are loose in scurvy, in purpura, and in mercurial salivation. They appear elongated, owing to retraction of the gums, in scurvy, sometimes in scrofula, and often in chronic gastritis and other prolonged disorders of the digestive organs. They become carious owing to the excessive use of saccharine and acid substances, especially in early life, to the abuse of mercury, to chronic indigestion, and to ricketty and scrofulous habits of body. Improper diet, at an early age, favours the occurrence of this change in the teeth; diseased teeth are always an indication of pre-existing disorder of the digestive organs, often connected with the abuse of spirituous liquors, or of sugar in its various uses; and they generally evince impaired vital power and resistance.

100. (*b.*) *The Gums* and lips are pale in anæmia and chlorosis, and after excessive hæmorrhage, or injudicious bloodletting. When they are covered by a similar mucus to that observed on the teeth (§ 98.), the diagnosis and prognosis are as above stated. They present a blue margin in cases of slow poisoning or contamination by the preparations of lead; and a red, spongy and swollen appearance from the use of mercury, from prolonged disorder of the digestive organs, in diabetes, in incipient scurvy, and in purpura. They become of a darker hue, more spongy, more retracted, and more disposed to bleed in scurvy and in chronic stomatitis. They are still more seriously affected in the ulcerative, gangrenous, and phagedenic forms of this malady. (See Art. Stomatitis.)

101. *B.* The Tongue presents diversified appearances depending — 1st. Upon the states of the several digestive functions; — 2d. Upon the nature of the disease; and 3d. Upon the existing constitutional disturbance, chiefly as respects organic nervous power, vascular action, and sanguineous contamination. In estimating the signs furnished by the tongue it should not be overlooked, that it may be coloured by medicines, by food and by drink, and be rendered drier than natural by breathing through the mouth; but it

is much less disposed to be affected by these causes in health than in disease.

102. *a. The mode of protruding*, of holding out, and of withdrawing, the tongue is always deserving attention. The tongue is protruded with difficulty in comatose, apoplectic and paralytic cases, owing chiefly to a weakened or paralysed state of the organ; and, in the more dangerous states of these diseases, it is either imperfectly protruded or not at all. In this latter case, either the existing insensibility prevents any attempt to execute the command, or the muscular power is so paralysed as to prevent the act of volition from being performed; and if it be executed, the tongue often remains protruded. A slow or tremulous protrusion; or tremor during the protrusion, of the tongue, is observed in many nervous complaints attended by debility or exhaustion, and more especially in low, typhoid or adynamic fevers. A ready, quick and steady protrusion and withdrawal of the tongue occur in diseases of excitement, in inflammatory affections, and whenever organic nervous power is not materially depressed, or when the cerebro-spinal influence is not impaired or suppressed, as in the stupor or sopor of low fever, or in comatose states. As long as the perceptive faculty is unimpaired and muscular power is not remarkably reduced or paralysed, these acts are usually naturally performed. The tongue is protruded to one side in cases of paralysis, especially in hemiplegia; but there is no certain correspondence between the side to which it is protruded and the affected side.

103. *b. The size* of the tongue varies in different diseases, and with variation in size there is often also variation in *form*. *Increased size* is caused by inflammatory action chiefly, this action being either *primary* (See TONGUE, *inflammation of*) or *consecutive*. It is the latter chiefly as a complication of angina, of scarlet fever, small-pox, of hysteria, epilepsy, syphilis, and as a consequence of mercurial action, or of poisons. The enlargement may, instead of being acute as in these cases, be chronic and the result of an hypertrophy or increased irritation of its tissues. With the enlargement may be connected several other appearances, which indicate prolonged chronic or visceral disease, as well as impaired constitutional or organic nervous power. The chief of these are—1st. A broad, flabby state, with more or less intumescence, and with indentations by the teeth on the edges of the tongue;—2d. A fissured or sulcated condition, the tongue appearing lobulated as well as enlarged; and 3d. A tumid and livid state, the surface being covered by a yellowish load, or a milk or cream-like mucus. The first and second of these occur chiefly in prolonged disorder of the digestive organs, or as consequences of mercurial action, or in connection with hepatic disease, &c.; the third more frequently as a result of diseases of the lungs, heart, and urinary and uterine organs. Swelling of the tongue is a dangerous sign in cerebral affections, and in cases of poisoning. It is also very unfavourable in exanthematous or continued fevers, especially the putro-adynamic and pestilential, and in scurvy, particularly when the swelling is great, or when the tongue is dark or livid, or is covered by a sanguineous or sanious exudation.

104. *c. Diminution* of the size of the tongue is usually much less remarkable than enlargement. The diminution may be more apparent than real, owing to contraction of the organ laterally, as well as to a partial retraction. In these cases the tongue is narrow and pointed, and indicates a most dangerous state of typhus, typhoid and adynamic fevers, of acute irritation or inflammation of the digestive organs, or of the brain or membranes, especially when it is also dry and red at the point and edges. Actual diminution of the size of the tongue is comparatively rare, as emaciation, even when extreme, affects but little this organ.

105. *d. The form* of the tongue is not materially different from that already stated — the chief modifications being in the breadth of the organ in relation to the length, in the narrowness and thickness of it, and in the fissured or lobulated appearance of its upper surface. But this surface may present other conditions. It may be so deeply indented or furrowed, or fissured, along the centre, from the root to nearly the point, as to appear almost divided into two halves, the sides of this indentation sometimes being more or less furred (§ 110.). This state occurs chiefly in chronic disease of the abdominal viscera, especially of the digestive organs, and indicates a most obstinate, although not a dangerous disease. The tongue when protruded may present either a convex or a concave appearance of its superior surface, or a double convexity, owing to the furrow along the centre. When either of these states is very remarkable then more or less irritation or inflammatory action of the abdominal organs is very frequently present. The lobulated state of the upper surface of the tongue is caused by more or less numerous fissures or indentations in various directions. It is generally connected with a tumid and convex condition of this surface, and is most frequently seen in chronic diseases of the liver or other digestive organs, in diseases of the heart, and in disorders of the female sexual organs.

106. *e. The humidity* of the tongue proceeds from the salivary secretion poured into the mouth, and very partially from the mucous secretions in the vicinity, and from the exhalations taking place in the surface of this part and the vicinity. The presence or absence of this humidity — the moisture or dryness of the tongue, is most important as respects the other states of this organ, and as regards the secretions and excretions, and the conditions of vital power, and of the circulating fluids. *Humidity* of the tongue is often very remarkable in cases of debility when all the secretions are free, and the blood uncontaminated. When it is very considerable, and is attended by *softness* of the organ, and by a flattened state of the fur, when fur has been present, as in convalescence from acute diseases, either tonics are required or lowering means should be avoided. When the tongue has been dry or furred, or both, then returning humidity and softness are always excellent signs, and especially when the surface becomes also more clean, or when the fur disappears or is flattened, the tongue and mouth being sufficiently moist, &c. In acute diseases, the humidity appears first at the sides of the tongue, and gradually extends, the other changes advancing with the increase of humidity, and being favoured by the state of the salivary secretion. As long as the tongue and mouth continue moist, in acute

maladies, a favourable opinion as to the issue may be entertained.

107. *f. Dryness* of the tongue is as unfavourable a sign as humidity is favourable. Dryness, however, may be occasioned by breathing through the mouth; but this will seldom produce it in a very marked degree, if febrile, or inflammatory action be not present. Dryness is most common in continued fevers, in the exanthemata, in inflammation of the abdominal viscera and of serous membranes, and in various other diseases of an acute and febrile nature. It is most remarkable, and presents either roughness, owing to the parched state of the papillæ, or fur, or a fissured or burnt appearance, often with a deeper or darker hue, in the most dangerous states of these maladies. The more extreme of these conditions of the tongue, and especially when they are not attended by thirst, are generally fatal indications. When the tongue has been furred and loaded, and subsequently becomes dry, rough or hard, and at the same time very dark, the furred surface being both dry and dark, or even black, a malignant or almost hopeless state may be inferred, owing chiefly to exhaustion of vital power and contamination of the circulating fluids, with arrest of the secretions. Humidity of the tongue rarely supervenes upon this extreme state, unless this dark appearance has been heightened by the substances taken into the mouth; but, in the less remarkable cases, the occurrence of humidity often takes place, and is a most favourable sign, inasmuch as it shows a return of the salivary secretion and of the secreting functions generally, especially when the skin also becomes less hot and dry, or more natural or perspirable.

108. *g. The colour* of the tongue should always be observed. The *natural* hue is favourable, and a return to it is an indication of a favourable crisis or change. The tongue may be more or less *pale*, and the pallor is commonly associated with a similar hue of the gums and lips, in cases of anæmia, of chlorosis, after large blood-lettings or hæmorrhages, and during prolonged chronic diseases, and affections of the spleen, owing either to a deficiency or to a poorness of blood. A very *red* tongue occurs chiefly in inflammations of the throat and pharynx, and in the exanthemata. A limitation of the redness to the point and edges is very general in acute irritation or inflammation of the digestive mucous surface, in gastric and bilious fevers, and in remittent and continued fevers, but in those latter, the surface and base of the tongue is at the same time loaded, coated or furred. If the tongue, after having been coated or furred, becomes *very red and clean*, in gastric fevers, and inflammatory or other acute diseases of the digestive or abdominal viscera, without returning strength or other favourable symptoms, a dangerous prognosis may be inferred; and more especially if the febrile symptoms be not abated, if the tongue be dry, and if the redness assume a glossy or varnished appearance. If, with this change, the tongue presents a yellowish red hue, and becomes glossy, dry and clean, great danger should be anticipated, especially in severe remittents, in bilious fevers, in putro-remittent or adynamic fevers, and in acute diseases of the liver and digestive canal. If the redness pass into a *brown*, *livid*, or *bluish* or deep *leaden hue*, whether the surface of the tongue be also moist or dry, or soft or hard, or furred or coated, or rough, or smooth and glossy, &c., an imperfectly changed, an insufficiently oxygenated, or a contaminated state of the blood may be inferred. This appearance, thus variously associated, according to the nature and stage of the malady, is observed in the most dangerous cases of asthenic or congestive pneumonia and bronchitis, especially when both lungs are affected, in organic diseases of the heart, in asthma, hydrothorax, in dangerous cases of hooping-cough, in the malignant or putro-adynamic, or asthenic forms of exanthematous and continued fevers, in pestilential maladies, in scurvy, and in the last stages of other diseases, or shortly before dissolution.

109. *h.* A *white* tongue is common in catarrhal and febrile disorders, in functional disturbances of the digestive and respiratory organs, and in the premonitory and invading stages of fevers — periodic, exanthematous, and continued — and of inflammations. A *clammy* state of the tongue, with a whitish, or yellowish-white, or milky load on the surface and base, with more or less humidity, is frequently seen in visceral diseases, in inflammatory affections of mucous surfaces, in the early stages of fevers, in connection with redness of the point and edges, and in puerperal fevers accompanied with a flabby and lurid appearance of the organ. A *loaded* tongue, the load varying in quantity, colour and consistence, occurs in bilious diseases, in the early stages of periodic and continued fevers, and in most of the maladies in which a clammy state is observed. These states, especially a loaded condition, are frequently complained of in the morning, soon after waking, by persons who are dyspeptic, or whose digestive organs, — stomach, liver or bowels, — have been much disordered; or who have been in the habit of taking suppers, or of smoking, or of drinking malt or other liquors previously to retiring to bed.

110. *i. A furred* tongue is always a serious indication. The fur resembles the pile on the surface of cotton velvets; and varies in length and thickness. It is often covered by a clammy or dirty mucus, the tongue being also coated on the surface and base by a load of fur and mucus. The colour of the fur varies from a greyish white to a brown or black, the surface generally becoming thus coated and dry or parched before the darker hues are observed. The origin of the fur has not been satisfactorily explained; but it may be attributed to a morbid development of the filiform papillæ of the tongue which become elongated during the progress of disease, and covered by the inspissated and dark mucus, which generally collects in the mouth during the diseases in which the tongue is furred. The surface of the fur, especially when thus coated, presents a more or less dark brown, or black hue, according to the duration, severity and danger of the disease, the deepness of the hue, however, being often much increased by the colouring properties of the substances taken into the mouth.

111. A furred state of the tongue is common in inflammations, especially of parenchymatous organs; in severe irritation of mucous surfaces and canals; in continued, exanthematous, typhoid or adynamic fevers; in diseases of the brain or of its membranes, and in most other acute maladies which advance to a dangerous condition. In the early stages of inflammations and continued

fevers, the filiform papillæ are merely erect and somewhat developed in length, giving the tongue a whitish hue. In the early stages of the exanthemata, especially in scarlatina, the fungiform papillæ on the sides, point, and middle, are very much enlarged, and appear very manifestly dispersed through the fur produced by the filiform papillæ. This appearance is also observed in many of the diseases of children, more particularly in those of the digestive organs. The dirty or clammy mucus, so frequently accompanying a furred tongue, loads the papillæ; and, with the progress of these maladies, especially as they proceed to an unfavourable or dangerous state, forms a darker or deeper coat, which often covers the whole upper surface of the organ, either in a continuous crust, or with more or less slight fissures in various directions.

112. The depth of colour, the dryness, the contraction or diminution of the surface of this fur and coating, and of the tongue itself, are important circumstances, and require close attention in the progress of acute diseases. An increase of either, and especially of all, of these indicates a proportionate increase of danger; whereas a diminution of these appearances, evinces a favourable issue, more particularly if the tongue becomes more moist and more clean, the fur and load disappearing from the point and sides, and progressively from the surface and base, the colour of the organ becoming at the same time more natural. If the coat or crust formed on the tongue be rapidly removed the surface thereby exposed being glossy, smooth, or fissured, and dark-coloured, or having a raw appearance, the prognosis is not improved by the occurrence. This change often proceeds from self-contamination of the blood in the course of the disease; the tongue frequently becoming still more dark, contracted, dry and even hard, towards a fatal issue.

113. With slight development of the filiform papillæ, the tongue sometimes presents *patches* which appear partially deprived either of papillæ, or of the epithelium covering the upper surface, which, at the same time, is broad or flabby, the edges of the tongue being occasionally also indented by the teeth. This appearance is observed chiefly in protracted disorders of the digestive organs, and in hypochondriasis, hysteria, and diseases of the uterine organs. It is always an indication of protracted and intractable disorder.

114. *k. An aphthous state* of the tongue, affecting chiefly the point and edges, is often observed in the last or fatal stage of tubercular consumption, and of several other visceral diseases. It is always a serious indication in the diseases of adults, even when unconnected with phthisis, especially in diseases of the digestive and urinary organs. (See Arts. Stomatitis, Thrush, and Tongue, *diseases of*.)

115. *l. The temperature* of the tongue is seldom materially affected. It is somewhat *increased* in inflammatory fevers, and in the early stages of exanthematous and continued fevers. It is diminished in all diseases, or towards the fatal issue of all maladies, in which the tongue presents a livid or dark hue. It is most diminished, becoming cool or cold, as pestilential cholera proceeds to a fatal termination.

116. C. The Salivary Secretion is intimately connected with the state of the tongue and mouth in disease, and with the indications furnished by the latter.—*a. Diminution* of the secretion both of saliva and mucus occurs at the commencement, and during the greater part of the progress of febrile and acute diseases; and with this diminution, which often amounts almost to suppression, these secretions become thick, viscid, or clammy, especially in continued, exanthematous, and low fevers, and in affections of the brain. They often assume a dark or dirty hue, thereby loading the tongue, and often collecting about the teeth, gums and lips. The bloody or sanious appearance of the interior of the mouth observed in scurvy and hæmagastric pestilence, is not produced by the saliva and mucus, but by the admixture with these of the semi-dissolved blood, exuded from the surfaces of the tongue and gums. A return of the salivary and mucous secretions, after their diminution or suppression, is always a very favourable sign, the detachment of the fur and load on the tongue during incipient convalescence being thereby favoured.

117. *b. Increased* salivary secretion — *ptyalism* — may be produced by any stimulus taken, or retained for a time in the mouth. It accompanies various affections of the gums and mouth, and the natural processes of teething in childhood. Whilst it is a salutary indication of teething, the sudden interruption or suppression of it is a very serious occurrence, and is very often a sign of incipient or advanced disease of the brain or its membranes. Ptyalism is produced by the constitutional or local operation of mercurials, iodine and iodides, and various other metallic and poisonous substances. (See Art. Poisons, *pluries.*) It attends, as a contingent, or intercurrent phenomenon, several diseases, as gastric catarrhs, chronic dyspepsia, hypochondriasis, hysteria, diseases of the pancreas, and occasionally small-pox. In the confluent form of this last malady, it is often a favourable symptom; but if it cease suddenly or prematurely it is generally a fatal indication.

118. *D.* The Throat *and fauces* present signs of disease not merely of the digestive canal, but also of the constitution. — *a. Relaxation* of the *uvula* is a symptom of general debility, in connection either with disorder of the stomach, or with catarrh, or with gastric catarrh or that state of catarrhal irritation of the digestive and respiratory mucous surfaces which often appears in spring and autumn, in connection with or even constituting catarrhal fevers. The elongation of the uvula, the result of relaxation, is often a cause of irritation to the epiglottis, and occasions or aggravates cough. And this having been admitted, to more than its full extent, it became a fashion to extirpate the uvula, without any regard to its functions, and without reference to the fact that the want of an uvula may be quite as injurious as an excess of it.

119. *b.* The *tonsils* or amygdalæ are often enlarged, either by acute disease — *tonsillitis* — or by a chronic congestion. Sometimes they are enlarged in connection with elongation of the uvula, and redness or chronic inflammation or irritation of the fauces, and pharynx. Chronic enlargement of the tonsils is not so frequently a sign of disorder of the digestive organs, as of a scrofulous diathesis, or of general derangement of health. In connection with redness of the fauces, palate, and pharynx, enlargement or redness of

the tonsils, is an indication of disorder or disease of the digestive organs, of exanthematous and gastric or bilious fevers, and often also of continued and typhoid fevers. This redness of the several parts of the throat, with redness of the point and edges of the tongue, and development of the fungiform papillæ, is very remarkable in the early periods of scarlatina, and frequently also of measles and small-pox. (See also Arts. Throat and Tonsils.)

120. *c. The secretions* of the throat are often materially affected. With increased redness they may be either diminished or augmented. *Dryness* of the throat attends the commencement or early stage of inflammation of the parts just mentioned (§ 119.). And, in cases where an injudicious and officious treatment has removed either the uvula, or the tonsils; dryness of the throat, and roughness or change of voice, have rewarded the confiding or credulous patient; the parts concerned in secreting, and in distributing, a lubricating mucus to the surface of the throat having been extirpated, as if nature had formed them for no purpose. During the more advanced stages of inflammatory irritation, the mucous secretion and watery exhalation from the throat are much *increased;* the same effect follows catarrh, catarrhal fevers and influenza; in which, as well as contingently on several diseases, increased secretion and exhalation are prominent affections.

121. E. Deglutition is often affected owing to disease either of the passages—of the throat, pharynx and œsophagus — which convey substances into the stomach; or of the brain, or of the structures surrounding and protecting it, especially the base of the brain and medulla oblongata. The diseases of the passages leading to the stomach, and the attending symptoms of difficult and interrupted deglutition, are considered in the articles Œsophagus, Throat, and Tonsils. *Dysphagia*, or difficult deglutition, and *Aphagia*, or impossibility of swallowing, are caused not only by lesions of these parts, but also by diseases of the brain or medulla oblongata, or of their envelopes, and by structural changes implicating the nerves supplying the tongue, pharynx and upper portion of the œsophagus. When swallowing is materially affected by these latter pathological conditions, then speech and voice are generally more or less disordered, or both deglutition and speech may be altogether lost. I saw a gentleman who had lost the faculties of deglutition, speech and voice. He complained of no other symptoms referrible to the head or cervical region; and was otherwise in good health. Deglutition partially returned after a time, but the power of articulation was never restored. He died suddenly. The body was not allowed to be inspected. Impaired or lost power of swallowing, with or without loss of speech but most commonly with partial or complete loss of this faculty, may either be the precursors of a more general attack of palsy or of apoplexy, or be the consequences of an attack of either or of both. But whether ushering in, or following a cerebral attack, it is always a most dangerous symptom. When a fatal issue does not supervene, the power of swallowing generally returns, either partially or altogether, before speech or articulation is restored.

122. In all these cases deglutition is im paired or lost owing to paralysis of the muscles concerned in this function, but it may be difficult, painful, impaired or impossible, in consequence of spasm of these muscles, or of some portion of the œsophagus, as in rabies canina or hydrophobia, and in hysteria, hypochondriasis, &c., in all which the difficulty of swallowing liquids is greater than that of taking more consistent substances. The dysphagia accompanying hysteria and other functional nervous affections is not further unfavourable, than that it indicates a greater severity of these affections. The aphagia of rabies is always a fatal sign, although it generally disappears before dissolution. Painful, difficult or impaired deglutition is often a symptom of the presence of flatus in the œsophagus, and in these cases, spasm of portions of the œsophagus often takes place. When swallowing is affected by this cause, flatulent eructations either precede, accompany, or follow the act; and the patient is generally subject to one or other of the forms of *indigestion*, or to *flatulence* during empty states of the stomach.

123. ii. The Appetites for Drink and Food are generally affected by disease.—*A. a. The desire for drink* is *diminished* in several diseases, and is in most of these a very unfavourable symptom, more especially when the tongue and mouth are dry, and other febrile symptoms are severe. In the advanced stages of fever, especially in continued and typhoid fevers, and in the advanced periods of inflammations, particularly of the brain or of its membranes, the absence of thirst or of a desire for fluids or drinks of any kind is a most dangerous, although not necessarily a fatal sign, especially in fever. In chronic diseases, the absence of a desire of drink is often present, and is merely an indication of the absence of febrile excitement; but, in the last stages of acute diseases and fevers, it shows the existence of a state of sensibility which is either associated with delirium, or about to pass into it, or into unconsciousness or coma.

124. *b. Increased desire* of drinks is generally present in all diseases caused by irritation or inflammation—in febrile maladies during the earlier stages, and before sensibility or consciousness becomes impaired. The supervention of thirst or an increase of it, in the course of chronic disease, is an indication of intercurrent irritation or inflammatory action. Its continuance after critical evacuations is an unfavourable circumstance. Thirst, in its extreme state, is present in the most dangerous cases of choleric pestilence, and in inflammations of the stomach, &c. Thirst, with an inability of drinking, is characteristic of rabies; and sometimes occurs in hysteria, hypochondriasis, but in a much less marked, and in a different form. The sudden cessation of thirst, or absence of the desire of drink, after thirst had been urgent, precedes unconsciousness or coma.

125. *c.* An appetite for *certain kinds of drink*, in preference to others, is observed in several maladies, — for iced water, or cold water, or for ice, in the stages of vascular excitement in fevers, inflammations, &c., especially in choleric pestilence and inflammations of the digestive canal;— for demulcent and emollient drinks, in affections of the respiratory organs; — for acid or acetous fluids, in chlorosis and disorders of the female sexual organs; — for vinous and restorative drinks in diseases of debility, in nervous disorders, and during convalescence from fevers. The appetite for these several kinds of drink, is an indication of

the nature of the malady, and is, in many cases, in accordance with the intentions of cure which should be adopted. The desire for intoxicating drinks is of itself a malady, which, when not gratified, is attended by distressing symptoms of exhaustion and nervousness.

126. *B. Desire of food* when moderate or natural is a favourable symptom in chronic affections.—*a. A diminution* or entire *loss* of this desire is present in most acute, and in many chronic diseases. With increased desire of drink diminished or lost desire for food is evinced. *Anorexia*, or loss of appetite, is often an indication of the impropriety of taking food, inasmuch as it occurs either in fevers, or in inflammations, or in other diseases of the stomach and digestive organs, in all which food would either be thrown off, or not digested, or be a cause of increased disorder. A diminution merely of the appetite is often caused by want of exercise, especially in the open air, and in aged or paralysed persons, for whom the demands of nutrition are neither great nor urgent. It is also observed in chronic affections, often, however, with a return of the desire, or with cravings after intervals. The loss of appetite is always complete at the commencement and early stages of fevers and acute diseases. If it continue during convalescence, a relapse, or some important sequela, or structural change, should be inferred.

127. *b. Increased appetite* is, in its various degrees, not only a symptom of disease, but often also a sign of approaching disease. Extremely increased appetite — *Bulimia* — *fames canina* — has been treated of in the article APPETITE. These states, only, of increase which are observed as a symptom of disease will be noticed at this place. Increased appetite is most frequently a consequence,—1st. of an increased demand for support and nutrition, as occurs during pregnancy, and in convalescence from acute or exhausting maladies, — 2d., or of a state of erythism, or irritation of the stomach and digestive organs, — 3d., or of irritation or disease of the nervous centres of animal life. Increased appetite in the early stages of fever, or of other acute diseases, is unfavourable, but if it occur in connection with other signs of improvement it is a favourable indication. If it be present without other signs of improvement, after anorexia has existed, a dangerous sequela is indicated. Increased appetite is frequent in all verminous diseases, owing to the irritation they produce, and the consumption of nutritious elements; and it is often caused by the use of stimulants — of wine, spices, hot sauces, &c. A great increase of appetite — or a keen, or ravenous, or craving appetite — often ushers in, or precedes for a short period, an attack of apoplexy, or of epilepsy, or palsy, or mania or phrenitis. Increased appetite very generally attends epilepsy in the intervals between the fits, and is the greatest before a severe paroxysm. It often also accompanies hemiplegia, and it indicates either an attack of apoplexy, or an exasperation of the paralytic seizure, at no very distant period. A craving for particular kinds or articles of food is observed in the course of both acute and chronic diseases, and is often suggested to the imagination of the patient by recollections of the past, or by the attendants; but whether these cravings convey a favourable or unfavourable import depends upon the effects they produce when the patient is allowed food. A craving for unnatural or improper kinds of food — *Pica* — or for articles that are not commonly used for food, sometimes occurs during pregnancy, in chlorosis, and in the course of several disorders of the female sexual organs. (See Art. APPETITE, VITIATED.)

128. If increased appetite become changed to loss of appetite, or to loathing of food upon taking a small portion only, chronic gastritis or structural change in the stomach may be inferred. A desire for animal food early in febrile diseases, or previously to convalescence, is an unfavourable sign. A keen appetite is generally produced by exercise in the open air; but it is also often the result of habit, and of want of occupation either mental or physical, especially when indulged. Excessive use of animal food is often progressive, the uses of certain kinds creating an increased desire for them, especially of pork. Persons who have thus indulged their appetite generally die prematurely, or seldom live beyond middle age, and are either carried off by apoplexy, by a mixed epileptic and apoplectic seizure, or become hemiplegic. If attacked by continued fever, or by small pox or scarlet fever, they seldom recover, the malady assuming either a comatose, or a putro-adynamic form.

129. *c. Loathing of food*, and *nausea* excited by certain kinds of food, are generally observed in the premonitory period of fevers and acute diseases, also in affections of the stomach. A dislike of flesh meats is very remarkable in these cases. A loathing of certain kinds of food is frequent in delicate, nervous, hysterical, and hypochondriacal persons. When it depends upon disorder of the digestive organs, nausea, horripilations, and even vomitings or retchings, often supervene. Prolonged loathing of food in chronic diseases augurs the presence of organic lesions. The occurrence of loathing in convalescence indicates either a relapse or the supervention of visceral change.

130. *d. Nausea* may proceed either from the state of the digestive organs, especially of the stomach, or from the nervous systems of organic and animal life. The digestive organs sympathise, through the medium chiefly of the organic nerves, with all the other abdominal and pelvic viscera, the stomach evincing this sympathy more particularly by nausea, or vomiting. The nausea sometimes observed in hysteria, in pregnancy, and in hypochondriasis, is generally also sympathetic of irritation transmitted through the medium of the ganglial nerves to the stomach. Nausea on the invasion, or at an early stage, of continued and exanthematous fevers is only an indication of the marked participation in the disorder of the whole œconomy, which the stomach generally evinces. Nausea, often attended by vomiting, accompanies epileptic seizures and diseases of the brain; and in these it is always a very serious or even a most dangerous symptom. Nausea may be produced by a disgusting sight, or even by the recollection of such; and, in these cases, the impression is conveyed from the brain, as in cases of organic lesions of the brain, by the communicating nerves to the organic nerves or ganglia supplying the stomach. The nausea and sickness produced by sea-voyages have been attributed to affection of the brain sympathetically conveyed to the stomach, but they appear to be more directly owing to an affection of the semilunar and other ganglia,

than to the state of the brain, which seldom betrays much disorder in cases of sea-sickness. Vomiting consequent upon fæcal obstruction is a most dangerous symptom, and is always fatal when the vomited matters have a fæcal odour. (See Art. Vomiting.)

131. *e. Various other symptomatic affections* of the stomach occur and furnish important information as to the nature, seat, and issue of disease. These affections are eructations, heart-burning, retchings and rumination, and are described, with their various relations, in the articles Flatulence, Indigestion, Pyrosis, Rumination, and Vomiting. To these I must refer the reader; and only adduce at this place a few remarks respecting flatulent and other eructations as a symptom of disease. *Eructations* either are flatulent, or consist of fluids, or of semi-digested articles, which may be sour or acid, or saltish, or alkaline, but very rarely the latter. Flatulent eructations occur not only in most affections of the stomach, but also in congestions and torpor of the liver, and in obstructions to the functions of this organ. They frequently depend upon a gouty diathesis, and attend, but more generally precede, an attack of this disease. They are common also in hysteria and hypochondriasis; the flatulence often rising in the œsophagus, and remaining for a time confined there by spasm, increasing disorder by pressing upon the heart and large vessels. Even when flatulence and flatulent eructations depend upon the diseases now mentioned, and especially when connected with biliary obstruction, it is more or less associated with acidity of the prima via. Fluid eructations often proceed from over-loading the stomach, and from organic lesions of the stomach, or liver, or spleen, or pancreas; and in these diseases they may be either tasteless, or sour, or saltish. These may also precede an attack of gout, or accompany calculous affections; but, when they are of long continuance, or are not materially influenced by treatment, they should be then referred to organic lesions either of the stomach, or of one of the collatitious organs. It should, however, not be overlooked, that the most dangerous diseases of these may occur without these eructations appearing in a very prominent form. As to the signs furnished by appearances of matters thrown off the stomach, see the article Vomiting.

132. iii. Intestinal Flatulence, as well as gastric flatulence, should not be imputed to decomposition of the ingesta, or of the contents of the canal, owing to their retention; but rather to irritation of the mucous surface, in connection with impaired tone of the muscular coat, and with general debility. Although certain ingesta may favour the generation of flatulence, or even furnish a portion of the gases producing it, especially in cases of intestinal flatulence, yet it cannot be disputed, that the gases which accumulate in the digestive canal are chiefly an exhalation from the villous surface. In some cases, especially at an advanced stage of diseases of the digestive tube, the accumulation of gas occasions a tense and tympanitic state of the abdomen, and generally increases the severity of the disease and the sufferings of the patient. Gaseous collections in the stomach or bowels, or in both, are apt to occur, in many diseases, as a contingent and intercurrent phenomenon; but in other maladies they are more distinctive symptoms, and should receive due attention, as evincing not merely the nature, but also the issue of the disease. These collections are most frequently formed in very young and in aged subjects, in persons of sedentary habits, in catarrhal irritation of the stomach and bowels; in the several affections and maladies of these viscera, and of the associated and connected organs; in the gouty diathesis and in the atonic forms of gout, in hysteria and hypochondriasis; in puerperal and adynamic fevers, and in obstructions of the intestines by any mechanical or other cause. These symptoms are aggravated by certain kinds of ingesta, especially by raw or bulky vegetables, and by peas, beans, or any preparations of these, also by hot spices, or by irritating and indigestible substances.

133. When the gaseous exhalation is attended by rumbling noises — by *borborygmi* — as in hysteria, a spasmodic or an irregular action of the muscular coats of the canal is present, propelling the distending flatus in various directions. Borborygmi in the course of low fevers sometimes precede a favourable crisis. The discharge of flatus by eructation is often of service in the more severe diseases in which gastric or intestinal flatulence are prominent symptoms; but the escape of it *per anum* is much more favourable, especially in ileus, in colicky affections, and in obstructions of the bowels. Intestinal, as well as gastric, flatulence is generally connected with acidity of the bowels, and often also with obstructed or morbid states of the biliary and intestinal secretions and excretions, and not only with these, but often also with a self-contaminated state of the circulating fluids, especially in the portal vessels. These states are more particularly manifested in the atonic forms of gout, in adynamic fevers, and occasionally in calculous or gravelly affections. In these diseases and contingently in many cases of other complaints, the deficiency of a healthy bile not merely renders the villous surface more prone to exhale a gaseous fluid, but also favours morbid changes in the intestinal contents, the fæcal excretions being morbid in colour, consistence, and smell; the odour being sour and offensive.

134. iv. The Intestinal Evacuations should receive the most attentive examinations in all diseases, but particularly in those which are severe or obstinate; and these examinations should be made in respect of the successive evacuations passed from the period of the previous visit. An inspection of the tongue, mouth, and throat, and an examination of the several regions of the abdomen, by pressure and percussion, should also be made, either immediately after or before, generally after, the stools have been examined, inasmuch as the state of these may suggest modifications in the examination of the abdomen.

135. The intestinal evacuations may be either too few, or too frequent — after protracted intervals, or at unusually short intervals. They may be variously disordered or unhealthy; and the discharge of them may be preceded and attended by much and diversified disorder. These severally as well as in connection will direct the diagnosis and prognosis of the physician. The derangements of defæcation — the disorders in which either the retention, or the frequent discharge, of the fæces, depend chiefly upon the states of the digestive canal, have been fully described in the

articles Costiveness and Constipation, Colic, Ileus, Concretions in the intestines, &c. and in those on Diarrhœa, Cholera, and Dysentery. These diseases being considered in connection with the more important complications they present in practice, and with the states of the intestinal evacuations, comparatively little remains to be noticed at this place.

136. *A. Retention or delayed evacuation* of the intestinal contents is observed in various diseases as an important symptom, independently of being itself a distressing disorder. — 1st. It is often a symptom of serious diseases of the digestive canal, of the liver, spleen, kidneys, and sexual organs; — 2d. It is frequently caused by mechanical obstructions furnished either by the parietes of some portion of the canal, or by substances retained in, or obstructing the passage through, the canal; — 3d. It may be entirely symptomatic of disease of the brain, spinal chord, and thin membranes, of hysteria, melancholy, mania, &c. — (*a.*) The remarks offered when treating of Costiveness and Constipation, of Colic and of diseases of the Cæcum and of the Colon, sufficiently elucidate many of the most important topics connected with constipation from disorders of the bowels themselves; and in gastritis, enteritis, hepatitis, and in other diseases of the abdominal viscera, costiveness and the appearance of the evacuations claim strict attention; the spontaneous return, or the easy production of intestinal evacuations, and a more natural or healthy appearance of them furnishing a most favourable indication; whilst a more obstinate retention, either with increase of painful symptoms, or with painful but abortive efforts at evacuation, evinces an increase of danger. In enteritis, the fæcal retention is occasioned chiefly by loss of the muscular or peristaltic action of the inflamed portion of bowel, and by the consequent distension of that and adjoining portions by flatus. The occurrence of evacuations indicates the removal, either partially or altogether, of these and other pathological conditions which caused the retention, and the subsidence of the inflammation, of which these conditions were the consequences.

137. (*b.*) The mechanical impediments furnished by portions of the parietes of the digestive canal, are either *spasmodic* or *structural*. *Spasm* of portions of the canal interrupting the passage of the fæcal contents towards the anus is very frequently observed in the course of Dysentery, Colic, Lead Colic, Hysteria, Gout, Hypochondriasis, &c., and sometimes contingently on other maladies. In many of these cases, the fæcal discharges are hard, lumpy, scybalous, &c., and are evacuated with antecedent or coëtaneous pain or gripings, and often also with flatus. In these complaints free and copious evacuations and a more natural state of the discharges are favourable circumstances. In most of these, the obstruction to evacuation is not only in the spasmodic state of portions of the bowels, but also partially in the inactive condition of other portions, or in the distension of these portions by flatus. *Structural changes* often take place in the parietes of the intestinal tube, and interrupt the passage of the fæces along the canal, by contracting or stricturing the intestine. Various lesions, external to the bowel, by pressing upon or strangulating a portion of it, produce a similar, or even more rapidly dangerous results. These alterations are severally described in the articles Colon, Digestive Canal and Duodenum, and when treating of Colic, Ileus, Constipation, Dysentery, &c.

138. Various substances, either formed in the digestive organs or passed into the stomach or bowels, and even intus-susceptions of portions of the intestines themselves, occasion fæcal obstruction, and always dangerous, and very often fatal consequences, as fully shown in the places just referred to, and when treating of Concretions, Biliary and Intestinal. Several indigestible substances may be swallowed, owing to a vitiated appetite, and be formed into masses more or less concrete or consistent, causing dangerous or even fatal results. A lady was in the habit of chewing and swallowing sealing-wax, and persisted in the practice for many months. Another, to whom I was also called, swallowed wax in every form, but chiefly as it existed in candles. Three young ladies came under my care who had long been in the habit of chewing and eating paper of various kinds. In all these, at first costiveness, and afterwards constipation, with colicky symptoms, and severe suffering, supervened. The perverted appetite was suspected and admitted. The means used to remove the obstruction were successful in all these cases, and brought away large and concrete masses of the substances thus unnaturally taken, mixed with mucus and fæcal accumulations. It is chiefly when intestinal obstructions are produced by one or other of the causes now mentioned, and, in much rarer instances, by intestinal worms, collected in large balls in hardened fæces and mucus, that the most dangerous consequences are to be dreaded from them.

139. (*c.*) In all inflammatory and organic diseases of the brain, spinal chord, or their membranes, constipation is a common symptom; but the danger does not depend upon the obstruction to fæcal evacuations in these cases, although it may be increased thereby. In these diseases the obstruction is generally overcome by medicine, but returns if the means for procuring evacuation be not frequently repeated. When vomiting accompanies constipation in these, the danger is increased, yet not in consequence of the latter being more obstinate or irremovable, but of a greater severity of the disease of which this is merely a symptom.

140. When obstruction to fæcal evacuation is followed by vomitings, the prognosis is unfavourable, especially if the obstruction have continued long. The danger increases in these cases if distension and tension of the abdomen, if pain or tenderness, or increased frequency of pulse, great debility or exhaustion, &c., supervene. It is still greater, the result being nearly always fatal, if the vomited matters have a fæcal smell; if flatulent distension be great and be attended by borborygmi, and if hiccup, or flatulent eructations be frequent or distressing. If the obstruction be suddenly removed, and evacuations more or less abundant be passed, pain or debility, or irritability of stomach still continuing, the prognosis is very unfavourable. If the pain and intestinal obstruction be suddenly removed, the vomitings, or hiccup, or abdominal distension still continuing, a fatal result will soon follow, and the sooner, the

weaker and more rapid and irregular the pulse, and the colder the extremities.

141. If constipation be attended by frequent abortive efforts to evacuate, or by tenesmus or straining, obstruction is generally present in the rectum, and often is produced by internal hæmorrhoids, or by stricture of the rectum, or by an enlarged ovarium or uterus, or by displacement of the uterus, or by enlarged prostate. Costiveness, in tubercular consumption, is more favourable than diarrhœa. An alternation of constipation and diarrhœa indicates serious chronic or structural disease of the digestive organs; and, in children, that the mesenteric glands are affected, chiefly enlarged. If constipation follow the sudden cessation of diarrhœa, and become obstinate, the prognosis is unfavourable; more especially if pain, tenderness, tension or distension of the abdomen be also present, and the tongue become dry or parched.

142. *B. Frequency of the intestinal evacuations* depends much on the age and habits of individuals. Infants evacuate the bowels twice or thrice daily, adults generally once only, sometimes twice, old persons even less frequently, and sedentary persons, who eat little, only once in two, three, or even in several days. Great frequency of evacuation, or purging, is always occasioned by disease of the digestive canal,—most frequently by irritation and hyperæmia of the digestive villous surface. The purging, when continuing for some time, constitutes diarrhœa, but when it ceases spontaneously after the bowels are unloaded, or after a short time, from the operation of medicine, it hardly amounts to the latter. Purging or diarrhœa is frequently owing to teething in children, and is a common complication in exanthematous fevers, and in gastro-enteric catarrh. In these cases it is also pathologically characterised by irritation with hyperæmia of the digestive villous surface. When it follows ingurgitation of food or intoxicating liquors to excess, or fæcal accumulations, or the irruption of accumulated bile into the bowels, it is thus similarly characterised, and generally subsides spontaneously, especially if due abstinence be adopted; but when it occurs as a complication of exanthematous or gastro enteric fevers, or in childbed fevers, the spontaneous cessation of it should not be trusted to, means to moderate or to arrest the inordinate action being then required.

143. When diarrhœa occurs in the course of adynamic or putro-adynamic fevers, asthenic inflammation of the intestinal villous surface and of Peyer's glands should be dreaded, and indeed it may have far advanced, especially if the stools present an ochry appearance. In such cases the danger is very great — very considerable if the diarrhœa have been of some duration, and extremely great if the stools have this appearance, or are intimately mixed with blood. Diarrhœa is also a most dangerous symptom when it supervenes upon chronic disease of the lungs, or of the liver, or spleen; and when it is connected with diseased mesenteric glands. Whenever the state of the evacuations shows either a protracted absence of bile, or an intermixture of blood, the prognosis should be unfavourable, and at a far advanced period of chronic or of hectic diseases, the danger should be considered as very great or extreme. When stools are passed immediately after substances have been received into the stomach, and more particularly if they have passed but little changed from the state in which they were taken, a fatal result may be expected in the great majority of instances, and disease of the mesenteric glands, and often also of other collatitious viscera, may be inferred.

144. Diarrhœa following vomiting often subsides spontaneously, especially when the cause consists of irritating ingesta, or overloading of the stomach. The same prognosis may be entertained if the diarrhœa follow constipation. If diarrhœa and vomiting, with or without spasms, be of considerable duration; if they occasion sinking, &c., or if they be produced by poisons of an irritant and depressing nature, danger should be inferred, especially if spasms be present and continue. (See Art. Cholera and Choleric Fever of Infants.) In most instances of diarrhœa, the previous history of the case, the diseases of which it is a consequence, or a complication; the existence and character of nervous symptoms; the amount of nervous or vital depression accompanying it; the nature and character of the prevailing diseases and of the dominant epidemic constitution, especially in connection with the exanthematous and continued fevers of which diarrhœa is so frequent a complication, should severally receive due consideration before we form conclusions either as to the result, or as to the indications of cure.

145. If diarrhœa be attended by pains following the course of the colon, or by tormina, then the colon may be considered as the chief seat of the affection. (See Art. Colon and Dysentery.) If the pains extend down the sacrum, or between the sacrum and pubis to the anus, or if they be accompanied by dysuria or ischuria and by tenesmus, the rectum is also affected. If diarrhœa or dysentery be attended by spasm of the sphincter ani, inflammation often with abrasion of the mucous surface in the vicinity may be inferred. If, in these diseases, the sphincter ani become relaxed or paralysed, an unfavourable opinion of the result may be entertained, and more especially if this occur in the course of diarrhœa complicating exanthematous, or typhoid or adynamic fevers.

146. If purging or diarrhœa, occurring in the course of visceral congestions, especially those of the liver or spleen, or in dropsical effusions, or in hypochondriacal affections, or as a sequela of agues, appear to give relief; or be followed by greater animation or increased strength and activity; and if either occur in the course of fevers and other acute diseases, as a critical evacuation, being moderate in frequency and continuance, and the evacuation of a more natural and healthy character, a very favourable issue may be expected. (See Art. Crisis.)

147. *C.* The Alvine Evacuations furnish important information as to the nature, complications and issue of both acute and chronic maladies. The fæces are altered by disease, in form, in consistence, in colour, in odour, in quantity, in the nature of their constituent elements or materials, and in the substances they contain, or that are passed with them.—(*a.*) The *form* and *consistence* of the evacuations vary with the age of the subject. The fæces in infants are pulpy and generally without form. In adults, they are usually

formed and more consistent, and in aged persons they either continue so, or become much harder and less bulky. At all ages, however, after infancy, they present every grade of consistence, from fluid to solid, according to the states or affections of the digestive organs. In cases of spasmodic or permanent stricture of the rectum or anus, or of internal hæmorrhoids, the evacuation is of small calibre, and often presents the appearance as if the fæcal accumulation were pressed through a diminished aperture, in continuous or broken, but considerable lengths, and of the same diameter. If there be enlargement of the prostate, or displacement of the womb, the evacuation is generally more or less flattened. The discharge may be lumpy, may resemble pigeons' eggs in form, be hard or very consistent, or scybalous. It is generally of these shapes in dysentery, colic, hysteria, sometimes in hypochondriasis and in several other diseases. In dysentery, these lumps or balls are accompanied either with a serous fluid, or with mucus mixed with blood, or with both, proceeding from the inflammatory irritation of the mucous membrane, accompanying the spasm of the muscular coats and the flatus, which chiefly occasion this form of the fæces in these complaints. Indeed whenever the stools present this lumpy or scybalous form, a spasmodic and flatulent state of the bowels, especially of the colon, may be inferred; and costiveness is generally present.

148. In some cases, especially in chronic dyspepsia, with impaired action of the liver, the stools are tenacious, figured and consistent, resembling putty in tenacity and sometimes also in colour. For these, stomachic or chologogue purgatives are generally required. In aged and sedentary persons, especially females, and often also when the liver is torpid or obstructed, fæcal matters accumulate in the sigmoid flexure of the colon, and in the rectum, distend the bowel, sometimes beyond the power of reaction or propulsion, and become hard and dry, owing to the absorption of their more fluid constituents. In this state, the lower bowel, especially the rectum, may be closely plugged up, the natural efforts to overcome the obstruction being accompanied with tormina, and continuing abortive until the concrete fæces are removed from the over-distended and obstructed rectum by mechanical aids.

149. (*b.*) *The colour* of the stools is very materially affected by the ingesta. In children the fæces in health are generally yellowish, in adults brown, in old persons dark brown. They are rendered much darker by port-wine or claret; by extract of liquorice, and by most of the dark fruits; and still darker or nearly black by all the preparations of iron, and by all articles of diet containing blood, as black puddings. They present a greenish hue, more or less dark or deep, after green vegetables, especially spinach. After rhubarb they are often yellow, and after magnesia or sulphur, or both, they are often paler than natural. The preparations of mercury often cause the fæces to assume a greenish hue, probably in consequence of the state of the biliary and intestinal secretions, and of acidity of the prima via. The compound decoction of aloes often imparts a darker hue to the stools.

150. (*c.*) *The odour* of the evacuations seldom continues the same as in health, in either acute or chronic diseases, and, when they return to their natural odour and colour, the circumstance is favourable. The more offensive the odour of the stools, the disorder of the intestinal secretions and excretions, the accumulations of them in the prima via, and the depression of vital power, may, either severally or conjoined, be inferred to have been also the more remarkable, unless indeed some preparation of sulphur have been taken and given the discharges the odour of sulphuretted hydrogen. If the stools have an earthy smell, and more especially if they have the odour of raw flesh or of putrid meat, a most unfavourable prognosis should be given, especially in gastric or intestinal fevers, in dysentery or in other diseases implicating the bowels. When the stools have a sour smell, then diarrhœa, or obstructed biliary discharge, or both, are generally present, and acidity of the intestinal contents clearly exists. This symptom is frequent in the diarrhœa of infants and children, and previously to, or during an attack of gout or rheumatism. The stools in pestilential and infectious maladies have a most offensive odour, which is peculiar to each malady, as in choleric pestilence, small-pox, &c.

151. (*d.*) *The colour* of the stools is variously changed in disease. It is pale, greyish, clay-like or nearly white, in all cases of biliary obstruction, whether accompanied with jaundice or not. In the more chronic biliary obstructions, and in the darker shades of jaundice, the colouring and other ingredients of the bile are altogether wanting, the stools are nearly white, unless when partially coloured by the ingesta; and the slightest indications of the presence of bile in the stools are to be viewed as a favourable occurrence. A greenish hue of the stools occurs in several disorders of the digestive organs, and in scrofulous or other organic diseases of the brain. A deep brown, or greenish-brown colour of the stools is generally owing to the passage of bile, which had been accumulated for some time in the gall-bladder and hepatic ducts, into the bowels; and a yellowish, or bright yellow tint may be imputed to the passage of recently formed bile into the intestines. Black stools are generally produced by the presence of blood, which may have passed into the stomach either from the nose, gums or mouth, or from the pharynx, or may have exuded from the internal surface of the stomach or small intestines. When blood is partially digested and intimately mixed with the contents of the bowels, the uniformly black hue presented by the fæces has been ascribed to black bile, which had been long retained in the biliary apparatus; others admitting that this colour is produced by blood have believed that the blood has escaped from the secreting structure of the liver along the ducts. In favour of this latter opinion we have no satisfactory evidence. The source of the colour in these doubtful cases may be determined by diluting the stools, when they will assume a more determinate red or green, according as the colour is owing to blood or to bile. An ochry colour of the stools is generally produced by numerous ulcers, seated in the glands of the villous surface, the blood exuded in small quantities from these being intimately mixed with the contents of the intestines, which are usually in these cases more or less fluid.

152. When blood is exuded in small quantity in any portion of the digestive canal above the valve of the cæcum, it is generally mixed intimately with the fæces. But, even when poured out in the small intestines, it may be passed by stool almost pure, although often grumous and uncoagulable, when the quantity is considerable or large, or the bowels irritable. Blood, imperfectly mixed with fæcal matters, dark-coloured and uncoagulated, may have come from either the small or large intestines. When it proceeds from the latter, it is often pure, red, and coagulable, and generally precedes or accompanies the evacuation. When it follows the passage of fæces, it commonly proceeds from the rectum, and is a consequence of internal piles. The blood thus discharged per anum, either alone or mixed with fæces, may be an exudation from an irritated portion of the villous surface, or a discharge from an ulcer or ulcers, or from a diseased vein, or an exudation occasioned by the association of irritation with a semi-dissolved condition of the blood itself. Bloody stools, either ochry, black, red, reddish brown, &c., occur in adynamic or typhoid fevers, in scurvy, in purpura, in organic diseases of the liver or spleen, in dysentery, in cancer implicating the digestive canal, in vicarious menstruation, hæmorrhoids, and contingently on several other maladies. Although the quantity of blood extravasated in these diseases may be barely sufficiently to colour the stool, yet it may be so great in other cases, as to excite fears of speedy dissolution, especially in fevers, and in organic lesions of the liver or spleen. These excessive hæmorrhages are always dangerous, especially in the more advanced stages of adynamic fevers. Nevertheless, recovery sometimes takes place, even in persons considerably advanced in life. I lately saw, within a short period of each other, two cases of this kind, with my friends Messrs. Houlton senr. and junr.; and, in these, although the loss of blood was remarkably great, recovery took place in both. The quantity of blood may be very small, or may merely streak the mucus, or discolour the serum, in which it is passed, and yet the danger may be extreme, as in ileus, volvulus, or intus-susceptions, in enteritis, in dysentery, the attendant symptoms more prominently evincing the danger. A raw, earthy, or putrid odour of the stools, in these cases, is the most unfavourable sign which can accompany the presence of blood in the stools, whatever may be its quantity.

153. The discharge of blood by stool in moderate quantity may produce relief in several diseases, especially in those of the liver or spleen, and in hæmorrhoids. But the relief may be only temporary, inasmuch as the disease or lesion, which occasioned it, may not be removed by it, and may proceed after a period of relief, this discharge recurring, or some other results being produced. In all cases of this kind the prognosis should depend upon the effects produced by the loss; by the existence or non-existence of anæmia, or of vital sinking; but, when such discharge occurs, in adynamic fevers, whatever may be the quantity — even no more than may be sufficient to impart an ochry appearance to the stools, then great danger is present.

154. (*e.*) *Bile* may be present in the evacuations in every conceivable quantity. The *stools* may even consist almost entirely of bile, or they may not contain a particle of it, as in choleric pestilence and in obstructive diseases of the biliary organs. A brown, or gingerbread-colour of the stools indicates a due proportion of both cystic and hepatic bile; a bright, but deep orange hue evinces a preponderance of hepatic bile, and, when the stools consist chiefly of a fluid of this tint, becoming darker after it is passed, then they may be viewed as bilious, or consisting in a great measure of bile mixed with more or less fæcal matters. Superabundance of bile in the stools is generally caused by chologogue purgatives prescribed at a time when the biliary ducts and gall-bladder have been loaded with this secretion, or by excitement of the liver, in connection with the influence of high ranges of temperature, or with passion or intemperance, or by any cause productive of irritation of the duodenum or of the common bile-duct.

155. The stools may present various forms and grades of consistence, both when well coloured and abounding with bile, and when deficient in colour and in bile. When thus deficient, they may be watery or serous, as in diarrhœa and pestilential cholera, or pultaceous or thin, as in jaundice, or in torpor and various states of obstruction, of the liver, or costive or hard in rarer cases of biliary obstruction, either with or without jaundice. Deficiency of bile, the stools presenting either of the characters just mentioned, but most frequently a thin or pultaceous consistence, is a symptom of torpor of the liver, as in many persons who have resided long in an intertropical climate, of obstruction of the ducts from constriction or contraction consequent upon inflammation, or from the impaction of a biliary calculus, and of the several organic changes described in the articles Jaundice, Gall-bladder and Ducts, Liver, &c.

156. (*f.*) The stools may contain more or less *serum*, as in the serous diarrhœa, which proceeds chiefly from inflammatory irritation of the mucous surface of the intestines, and which presents a brownish, or dark brown hue, in the more chronic cases, and when the liver or spleen is implicated; or they may consist almost entirely of serum, containing small albuminous flocculi, and present a pale and turbid appearance, or resemble rice-water, as in the diarrhœa of choleric pestilence, in which they are frequent and most abundant, and constitute the most dangerous symptoms of the malady. The continuance of pale, turbid or serous evacuations, without any appearance of bile, is always a dangerous circumstance, especially after rational means have been used to arrest them, and to procure a secretion of bile, or when they are very forcibly discharged or squirted from the anus. In pale, watery or serous stools, insufficiently coloured with bile, especially when passed frequently, and the affection having been of some considerable duration, substances which had been recently taken into the stomach are often passed either but little or not at all changed from the state in which they had been swallowed. This *Lienteric form* of diarrhœa is always most unfavourable, especially in infants and children, after weaning, or during dentition, or that have been deprived of their nurses' milk. (See Art. Diarrhœa, § 12.) The occurrence of serous diarrhœa with vomiting in

infants and children in warm summers and autumns, indicates serious and often very dangerous disease, especially when attended by fever. (See Art. Choleric Fever of Infants.)

157. Various substances, foreign to a natural state of the evacuations, are sometimes found in them, besides serum and blood. These are chiefly mucus, pus, fibro-albuminous exudations, fatty substances, cholestrine, biliary calculi, various kinds of intestinal concretion, worms either dead or living, portions of the mucous coat detached from the subjacent tissues, and even portions of intestine thrown off, in consequence of intus-susception and the consequent changes. These severally require but little remark.—*a. Mucus* occurs in *Dysentery* and *Diarrhœa*, and is often mixed with serum and pellets, or lumps of fæces. In the mucous state of the stools, the follicular apparatus, with the villous surface, is chiefly inflamed; but this appearance may pass into a watery or serous condition, or even into a mixed state, in which the evacuations are more or less streaked with blood as in dysentery. If ulceration supervene, the evacuations contain sanious matters, or blood in larger quantities.—*b. Puriform* stools, or an admixture of *pus*, with fæcal matters, may follow mucous evacuations, as in chronic diarrhœa, or chronic dysentery, especially when the puriform matter is much diluted or mixed with mucus; but, when it is present alone, or in large quantity and unmixed, or but little mixed with fæces, then the rupture of an abscess, seated either in the liver, or in the spleen, or in the vicinity of the spinal column, into some part of the intestines, may be inferred. A change of mucous to serous, or to muco-puriform, or to sero-sanguineous, or to sanious, or to puriform, stools, or to intestinal hæmorrhage, indicates a progressive advance of disease — generally of structural change; inflammatory irritation advancing to suppuration or ulceration, with the several changes described when treating of Diarrhœa, Dysentery, and Fever.—*c.* The passage of *fatty substances* in the stools occurs in rare instances, and has been observed chiefly in malignant and chronic visceral diseases, as in those of the liver, pancreas, duodenum and lungs. The other substances sometimes passed from the bowels, of which no notice need be taken at this place, are described in the article Concretions, *intestinal*, and in the other articles on diseases of the Intestines, &c., — on Worms, &c.

158. (*g.*) In all cases in which it is necessary to examine the state of the intestinal evacuations, and, indeed, in almost every case which comes before the physician, the several regions, not only of the chest, but also of the abdomen, should be carefully examined by percussion, and by pressure, directed according to the peculiarities of individual cases; and the sensations of the patient, as well as the sounds emitted, should be carefully considered. When pain is experienced either previously to, or during, or after evacuations, its character and connection with defæcation ought to be ascertained. In addition to these points, the strength, nutrition, and vital manifestations of the patient, as well as the performance of the several excreting functions, should receive attention. (See Art. Abdomen).

159. IV. Symptoms and Signs connected with the Circulating Systems.—When treating of Auscultation, of the Aorta, of the Arteries, of the Blood, of the Heart, of the Lymphatic and Lacteal System and Glands, of the Pulse, and of the Veins, the Semeiology *of the Circulating Systems* was fully considered, especially as respects diseases of these systems. It therefore only remains for me, at this place, to notice only those topics which have either been omitted or insufficiently discussed under these heads.—

160. i. In the articles on Auscultaton and Heart and Pericardium, I have described the physical signs of the heart and its capsule. The healthy and morbid sounds of the heart were topics of discussion when these were written, and they still are by no means satisfactorily determined. The interruptions, obstructions, or difficulties, to the passage of the blood through the several cavities and orifices of the heart, besides being accompanied by certain physical signs, described under these heads, give rise to several physiological or functional symptoms which ought also to receive due attention. The chief of these are — 1st. Short or difficult breathing, varying from a scarcely appreciable disturbance to dyspnœa or to orthopnœa; and often at first overlooked, or hardly complained of unless when ascending stairs, or a height. — 2d. Attacks of faintness, or of syncope, followed or not by palpitations, &c.; — 3d. Paroxysms of difficulty of breathing, or startings from sleep, especially about one of the earliest hours in the morning. — 4th. A sensation of sinking, or of suffocation, or of dissolution, upon walking quickly, or against the wind, or upon any physical exertion. — 5th. Congestion of the brain, owing to obstructed return of blood, occasioning vertigo, head-ache, or apoplexy, palsy, &c., if not prevented by epistaxis. — 6th. Congestions of the lungs, often causing hæmoptysis, pulmonary apoplexy, œdema of the lungs, or serous effusions into the thoracic cavities. — 7th. Œdema of the lower and upper extremities, and often also of the face, in the morning; or asphyxia by accumulations of mucus in the bronchi.— 8th. Lividity of the lips, tongue, gums, fingers and nails. These cannot, individually, be assigned to certain or determinate organic lesions, but may severally accompany or supervene upon one or more of these lesions. Certain of them may even be present without any structural change of the organ, as shortness or difficulty of breathing may be a symptom of anæmia, or of chlorosis. Faintness or syncope, with or without a feeling of dissolution, is most frequent in passive dilatations of the cavities, or in cases of fatty softening of the parietes, of the heart, with or without ossification of the coronary arteries.

161. *Palpitations*, as well as irregularities, and intermissions of the heart's contractions, &c., attend several organic lesions of the organ, and they may occur independently of any of these, and merely as a consequence of weakness or other disorder of the digestive organs, or of irritation of some viscus with which the heart sympathises. When palpitations follow mental emotions or sudden shocks they soon subside, or are followed by depression or faintness; or when they are consequent upon hysteria, or irritation or excitement of the sexual organs, the heart's action returns to its normal state. But, in cases of chronic debility, of exhaustion from prolonged

discharges, or from over-exertion or from inanition, or from prolonged anxiety, even independently of any manifest organic lesion, palpitations may frequently return, be alternated with faintness, or with irregularity of action, or even be characterised by such irregularity. In these latter circumstances, organic nervous power is more or less impaired, as respects the heart, especially in cases of faintness with or without any of these states of irregularity; or this power is irregularly distributed or determined, as in cases of nervous palpitation, in most cases of which it is also considerably weakened; the impaired tone of the muscular coats of the digestive canal, also generally present in these cases, admitting of flatulent distensions and fæcal accumulations, and thereby increasing the cardiac disorder. Indeed the parietes of the heart very often participate in the impaired vigour or tone of the coats of the stomach and bowels, flatulent distension of these impeding or interrupting the return of blood to the auricles, and thus preventing either the filling, or the dilatation of the cavities of the heart. When palpitations, attacks of faintness, or irregularity or intermission of the heart's action take place without being attended by any auscultatory sign, impaired influence or energy of the organic nervous system — constitutional or organic nervous debility is then generally present, although some change of structure, not indicated by the impulse or sounds of the heart, may also be present, as in cases of fatty softening, or of impaired nutrition of the parietes of the organ, or of disease of the coronary arteries. When treating of diseases of the HEART, in 1836, I directed attention to fatty degeneration of the substance of the organ (see that Art. §§ 224. *et seq.*); but, although this change may be admitted to be a consequence of impaired or morbid nutrition of the organ, often in consequence of ossific or other deposits in the coats of the coronary arteries, yet both softening and impaired nutrition of the muscular structure of the heart may take place without fatty degeneration in any very manifest degree being present. In all such cases, however, faintness, remarkable shortness of breathing, a sense of dissolution on walking fast, or on exertion, are generally observed.

162. ii. CONGESTION OF THE CAVITIES OF THE HEART may occur, either from general vascular plethora, or from a greater or more rapid return of blood to the right side of the heart than can be sent onwards by the ventricle, or from weakness, or dilatation of the parietes of the organ, or from obstruction to the circulation by material or mechanical causes. Either of these pathological conditions may produce this effect, or any two, or all of them may exist in the same case, and may even, without any further appreciable change, either terminate life or place it in imminent jeopardy, the distension of the cavities having been too great to be removed by the impaired or exhausted power of their parietes, or the material obstruction being too great or prolonged to be overcome by the weakened action of these parietes. In cases of this kind the patient experiences, whichever of these pathological states obtain, extreme oppression and a feeling of distension in the cardiac region, with great alarum, choking, dyspnœa, or orthopnœa, and often also with a sense of impending dissolution. The congestion is not limited to the cavities of the heart, but extends to the large vessels, especially to the veins, and the action of the organ is either weak, or irregular, or tumultuous and inefficient. The congestion is evidently connected with over distension of the cavities, as shown by the increased sphere of dulness on percussion, by pain in the left shoulder, or under the shoulder-blade, often extending to the arm. Death may ensue if the congestion be not removed, partially or altogether, either by stimulating or reinforcing the power and action of the heart, or by diminishing the distending mass of blood by depletion, or by the combination of both. When this event takes place, it may be imputed to some other pathological state than this, as to spasm of the heart, especially when the orifices, valves and parietes of the heart present no very manifest lesion, the post-mortem changes, or even the last struggles of existence removing the congestion, either wholly or in part, by which life had been extinguished. The slighter states of congestion of the heart are frequently present in *Hysteria*. (See Arts. CONGESTION and HEART, *Pleuries.*)

163. iii. THE SYMPTOMS AND SIGNS FURNISHED BY THE ARTERIAL AND VENOUS SYSTEMS.—Little remains to be added to what has already been advanced on this subject in the articles AORTA, ARTERIES, PULSE, and VEINS, to which the reader may be referred. When treating of the *Pulse* I have pointed out the SEMEIOLOGY, comprising both the *diagnosis* and *prognosis*, of arterial action. There is generally heard, by means of the stethoscope, a dull weak sound in the tract of the larger arteries, and this sound is variously modified, according to the state of the blood and the thickness and tone of the arterial parietes. If the blood be thin, or watery, or poor in hæmatoglobuline, or if the arteries be thin, and the blood deficient as respects the capacity of the vessels, the sound of the arteries at every systole of the ventricles is clearer and approaches nearer to a bellows or blowing sound. This sound is single and ceases with the systole of the ventricles. Pressure on the artery developes this sound, which is imputed to the friction of the blood-current or wave against the coats of the artery at each contraction of the ventricle.

164. *A. Morbid arterial sounds* are either *simple* or single or *double.*—*a.* The *simple* or intermitting bellows-sound is observed when tumours press on arteries, in aneurisms, in cartilaginous and ossific deposits in the coats of arteries, and when the circulation is accelerated, especially in chlorotic or anæmied persons, and after large losses of blood. It is generally sibillous in tone or character, varies in strength and loudness, and is isochronous with the termination of the systole of the ventricles. — *b.* The *double* or continuous bellows-sounds are heard chiefly in the carotid and subclavian arteries, but seldom with equal strength in both. Of these two or double sounds, the first is the stronger; and when they are loud or high, they become whizzing, buzzing, rumbling or piping, or sibillous; but pressure on the artery, the position of the head, &c., produce various modifications of these sounds, which, however, are generally loudest with the systole of the ventricles.

165. *B. The Capillary vessels* of various parts of the surface, especially in febrile, exanthematous

and cachectic diseases, furnish indications of some importance as respects vascular action and vital power. Pressure in cases characterised by redness or discolouration of parts of the external surface often, indeed generally, shows the cause, whether this be capillary injection or congestion, or extravasation. If the last, pressure does not materially affect the discolouration. In the first and second of these causes, pressure momentarily removes the discolouration; and the rapidity of the return of blood into the emptied capillaries is an indication of the rapidity of the circulation. When the colour is florid, the circulation is active, and vital power is not very manifestly impaired, but when it is dark-red, purplish or livid, the capillary congestion is the consequence of impaired vital power, and the circulation through the capillaries is sluggish or impeded. The capillaries become impaired more and more in vital tone with the advance of age, and are subject to the same structural changes as are described when treating of these changes in the coats of the ARTERIES (§§ 38. *et seq.*). When treating of these changes (in 1831), I described the *atheromatous* matter deposited in the walls of the arteries, as "a suety substance which is greasy to the touch;" and, although much more recently stated to consist of fat, or to be fatty, yet I believe that the description I have there given (see ARTERIES, § 59.) to be the more correct, as with fat other chemical constituents and animal products are conjoined.

166. *C. The veins* furnish indications of pathological states by their size and distension, by their varicose conditions, by the rapidity of their distension when pressure is applied in their course to the heart, and by their pulsations. The veins in the temples, face and neck are distended in cases of congestion of, and vascular determination to, the brain; and when this state is viewed in connection with other symptoms, the distension not being caused by attendant convulsions, then vascular depletion is generally required. A distended or varicose state of the veins in any of the extremities evinces obstruction of the venous trunk, or large branches, owing either to obliteration, pressure or other changes described in the article VEINS. The rapidity with which the veins refill, after having been emptied by friction, followed by pressure in their courses, as well as their size and fulness, serves to show the degree of fulness, or of deficiency, of blood in the system. The veins are small in youth, and in corpulent persons; they are large in the aged, and in the emaciated, this state admitting and showing fulness or enlargement of the veins, especially of the extremities. In the aged the veins lose their tonicity, and are more prone to congestion, and to retarded or obstructed circulation, especially when the circulation has to overcome the gravity of the column of blood in the veins.

167. A venous pulse is sometimes seen. It occasionally results from the continuation of the heart's action through the capillaries to the veins, when this action is inordinately excited, and is owing in some respects to the reaction of the capillaries upon the distension caused by the contraction of the ventricle, impelling the blood-wave onwards. The pulsation in other cases may be caused by an artery lying under or near a vein; and in some instances the pulsation is retrograde, as in the jugular veins, and in these it is a most important sign of cardiac disease, and is produced by contraction of the right ventricle, and regurgitation of blood, owing to dilatation of the right ventriculo-auricular orifice, or to imperfection of its valve.

168. *D. The Blood itself* furnishes most important signs of the nature and probable issue of disease. Of the signs which this fluid — vital in its relation with the several viscera, but more especially with the ganglia and ganglial nerves which supply the vascular systems — presents in disease particular notice has been taken when treating of the several forms and complications of disease, in the articles specially devoted to them, as well as in the comprehensive article on *the changes observed in the blood in disease.* (See Art. BLOOD.) To these, but more especially to this last, I must refer the reader, as nothing of any interest or of the least importance has been added to our knowledge beyond what may be found under those heads, and more particularly the last. *Spontaneous discharges* of blood and the sources and appearances of the blood thus discharged, furnish very important pathological and prognostic indications, but these are fully considered in the article on HÆMORRHAGE.

169. iv. THE LYMPHATIC SYSTEM—*vessels and glands.*—This system furnishes but few signs of disease beyond those which appertain to the maladies occasionally seated in them; and these signs are described in the articles on the LYMPHATICS and GLANDS, SCROFULA and PESTILENCE, GLANDULAR. Enlargements, inflammations, &c., of the lymphatic glands, and inflammation of the lymphatics themselves, are generally produced by some irritation, sore, or puncture, or by the inoculation of some poison in a situation near to, or beyond the seats of these affections. Enlargement of the glands near the base of the cranium, or in the upper region of the neck, is often observed in cases of scrofulous or tubercular meningitis and softening of the brain, in young subjects, either with or without effusion of serum in the ventricles, or between the membranes; and similar affections of the glands, either near the sternum, the clavicles, or arm-pits not infrequently precede or accompany the development of tubercles in the lungs. Enlargement, inflammation, suppuration, &c., of the glands, and even inflammation of the lymphatics, followed by disease of the glands, are very frequently occasioned by the application or inoculation of some virus, or poison, or by sores or irritation, as often shown by the introduction of the syphilitic poison into the frame, and by poisoned wounds or punctures. But independently of these causes and sources of contamination, the lymphatic glands are sometimes enlarged or congested in weak and delicate subjects, and they are occasionally asthenically inflamed and disorganised in the course of pestilential and malignant fevers; but most frequently and especially in the plague, in which pestilence the affection of these glands constitutes a distinguishing feature.

170. V. SYMPTOMS AND SIGNS OF THE RESPIRATORY FUNCTION.—These symptoms are of the greatest importance in respect not only of the diseases seated in the organs of respiration, but also of all other maladies to which the frame is liable. More or less disturbance of the respiratory func-

tion very often attends diseases of the heart and large vessels, and the advanced stages especially of diseases of the abdominal viscera, of febrile and constitutional maladies, and of affections of the brain. When treating of Auscultation, of the Chest, of the Bronchi, Larynx and Lungs, the signs and symptoms of the function of respiration, were described with reference chiefly to diseases implicating that function. Besides the signs furnished by auscultation, percussion, and inspection and admeasurement of the chest, several other means have been recently suggested of furnishing signs of pulmonary disease, and these have reference chiefly to the determination of the quantity of air received and discharged from the lungs at each inspiration and expiration, and of the power with which these respiratory acts are performed. For this purpose Dr. Hutchinson has invented an apparatus which he has termed a *spirometer;* and in order to show the movements of the chest in health and disease, Dr. Sibson has furnished an instrument, which is called a *chest measurer*. My limits prevent me from describing these and their application to the diagnosis of pulmonary maladies, and oblige me to refer the reader for all that should be known respecting them to the *Transactions of the Medical and Chirurgical Society*, (vols. xxix. p. 137., and xxxi. p. 353.) These means of diagnosis are of more or less service, especially in doubtful or difficult cases; but they should not be confided in further than that they are useful aids to the means previously employed, and to the rational symptoms furnished by the maladies of the respiratory organs. In all diseases, whether of these, or of other organs, the *voice* and *breathing* of the patient demand the strictest attention. The Voice is especially considered in a separate article; the *respiration* or breathing will be briefly noticed at this place.

171. i. Respiration is influenced or modified by age, by sex, by temperament, by the habit of body, by mental emotions, by the states of the atmosphere, by the positions of the body, and by the sleeping and waking states, and most remarkably by disease. Of certain of these little need be said. Temperament influences the respiration chiefly in connection with the conditions of the atmosphere, and with mental emotions, the nervous, susceptible, and irritable temperaments experiencing a greater frequency of respiration during warm and humid states of the air, and when the mental emotions are more or less excited. Persons of a full habit of body, and the subjects of obesity, respire more frequently, and receive less air into the lungs at each inspiration, than the thin or the more slenderly formed; and the short in stature have a somewhat less capacity of the lungs than the tall. Much, however, depends upon the breadth or width of the chest. A person when standing or sitting breathes more fully and freely than when lying down or reclining upon either side. Hence in bronchitis, in pneumonia of both lungs, and in cases of effusion into both pleural cavities, the patient cannot lie upon either side, for this position in some measure extinguishes the motions of the side of the chest upon which he lies, and increases the difficulty of respiration. Respiration during sleep depends very much upon the position and upon the habit of body, and upon the state of the stomach.

172. *Respiration during disease* should be examined — 1st. By observing the motions of the chest, and the phenomena attending inspiration and expiration; — 2d. By auscultation, or by listening to the sounds produced by respiration in the several regions of the thorax. The *second* of these modes is considered under the head Auscultation; it furnishes chiefly signs of disease of the respiratory organs, or rather those changes of respiration which diseases of these organs produce. The first not merely evinces diseases of the respiratory organs, but also gives more or less information as to the states of the vascular system, of the abdominal viscera, and of the brain. To this *first mode* of examination a brief notice is to be directed. Attention should be paid — 1st. To the frequency and quickness of the respirations; — 2d. To the motions and degrees of expansion in the several regions; — 3d. To the states of the nostrils and mouth during respiration; — 4th. To the uniformity, the ease, or the exertion of respiration; and the relations, in frequency and exertion, of the individual respirations to each other; — 5th The states of expiration in relation to inspiration; — 6th. The sensations experienced by the patient during the acts of inspiration and expiration; — 7th. The states of the expired air, chiefly in respect of temperature and odour.

173. *a.* The *frequency* and *quickness* of breathing may each exist independently of the other. Respiration is more *frequent* than in health, when a portion of the lungs can no longer perform its functions, as in pneumonia, tubercular consumption, &c., or when the lungs are more generally affected as in bronchitis, or prevented from expanding by pleural effusions, by incurvations of the spine, or by the invasion of the thorax by abdominal or other tumours, or effusions &c. It is also more frequent when the circulation is more rapid, than in health, and passes more rapidly, or in larger quantity, through the lungs, as in febrile maladies; and when the lungs are congested by impeded circulation through the heart. The prognosis of increased frequency of breathing depends upon these causes — upon the nature of the one producing it. In febrile diseases, the less frequent the respiration relatively to the amount of fever, the more favourable is the prognosis. The breathing even in the most unfavourable circumstances very rarely amounts to sixty in a minute. Respiration may be more *rare* or *less frequent*, than in health, as when the heart's action is impeded or rendered slow, or when the brain is congested, or the basilar parts of the brain, or medulla oblongata, or cervical portion of the spinal chord, is congested or pressed upon, or in syncope, catalepsy, structural changes of the substance of the heart; in sopor, coma, or apoplexy, or in certain states of paralysis; and during the extreme exhaustion preceding dissolution.

174. *Quickness* of respiration, especially of inspiration, arises from a more rapid action of the muscles of respiration occasioned by either weakness or fatigue of those muscles consequent on paroxysms of cough, as in pneumonia, bronchitis, pertussis, or on great muscular exertions, or on pleural effusions; and in many of these cases, as in pleuritis, in pleuro-pneumonia, in pericarditis, &c., the breathing may be quick and yet less frequent than natural, especially when respiration is attended by pain. Quickness increases the danger of frequency of respiration, especially in pneu-

monia, pleurisy, tubercular, and other organic maladies. *Slowness* of breathing is very often an attendant of diminished frequency, especially in those maladies, with which this latter is mentioned in connection. When it occurs in cases of extreme exhaustion, or at a far advanced stage of acute or chronic disease, with a small, weak, or irregular pulse, sinking of the features, cold or clammy extremities, &c., it indicates approaching dissolution. But it may also occur, although not as a consequence of serious disease, as in these circumstances, in cases of nervous debility, during attacks of faintness, or it may usher in hysterical syncope, or catalepsy, and be unattended by danger.

175. *b.* The *motions* and degree of *expansion* of the chest vary much in different individuals in the same disease. The *motions* of the chest, in the several thoracic regions, should be observed, when the clothes are removed; and any difference in the degree or extent, or quickness of motion in either side, ought to be noted. Uniformity of the motions of both sides of the chest is an indication of more or less uniformity of the states of the parts contained in each. But if this uniformity is only partial, if it be absent in any region, pleuro-pneumonia, tubercular formations, pleuritic effusions or adhesions, or other structural lesions, may be inferred to exist in the region where the motion is impaired or deficient, and the prognosis is unfavourable, or should be given with much caution.

176. According to the degree of expansion of the chest, respiration is *large*, or *full*, or *small*, or very small or shallow. If the breathing be full or large, the chest expanding freely and naturally, the rhythm being equal or normal, a favourable opinion may so far be entertained; but if this state of respiration be also rare or slow, or if the rhythm be unequal, oppression or congestion of the brain, as in nervous fevers, or sopor or coma, or apoplexy should be apprehended, if not actually present; or the accession of convulsions may be expected, especially in children. Respiration may be very great or large, and yet the quantity of air received into the lungs may be very small, the lungs being obstructed by disease of the bronchi, or of their substance, or by emphysema or pleural effusions. A *small* or shallow respiration accompanies pleuritis, pleuro-pneumonia, pericarditis, hepatitis, and diaphragmitis, also peritonitis, gastritis and enteritis, owing to the increased pain or uneasiness occasioned by a fuller or larger expansion of the chest; and is an unfavourable sign especially when it is attended by much debility or a sense of sinking, or by some degree of quickness, or by a sudden stop.

177. If the rhythm, or intervals between the respirations be irregular, or of unequal duration, an unfavourable opinion may be entertained, in those diseases affecting the thoracic organs and brain, and in the far advanced period of other severe diseases, more especially if, with irregularity of rhythm, there also be inequality of the fulness, greatness, and quickness of the respiration, a great respiration following, or alternating with a small one. When the respirations are affected by spasms, or by sighing, they are exceptions to this rule. A quick respiration, or a small one suddenly cut short, or interrupted by pain, or by the increase of it, is characteristic of pleuritis, pleuro-pneumonia, diaphragmitis, peritonitis, gastritis, &c.

178. *c. The States of the Nostrils and Mouth* during respiration often indicate the issue at far advanced stages of the disease. The expansion of the nostrils or alæ nasi at each inspiration indicates a great want of pure air in the lungs, and evinces great danger in all diseases of the pulmonary apparatus. The patient often breathes entirely by the mouth in diseases of debility or exhaustion, or at an advanced stage of acute maladies, especially in dangerous diseases of the brain, and the low or typhoid forms of fever, the tongue and mouth becoming more parched by the passage of air. During respiration various morbid sounds are produced, chiefly by the posterior nares, and by the larynx and pharynx which possess some prognostic significance. *Snoring* occurs during the sleep of plethoric, or other persons even in health, when the mouth is partially open, and occasionally in disease, especially in apoplexy. A *stertorous* breathing is always morbid, and is of much more importance than snoring, which is generally produced by inspiration, stertor chiefly by expiration through the nose and is a dangerous symptom in apoplexy. Expiration entirely by the mouth, with a puffing or blowing sound, is still more dangerous in this malady.

179. *d. The Ease, Uniformity, and degree of Exertion required in respiration.*—Respiration, as respects the exertion made in its performance, may be easy, weak, strong, difficult, or strangulating. (*a.*) An *easy*, *quiet* and regular or uniform respiration, without sighing or cough, is always a favourable sign, especially in febrile affections, and always renders other symptoms, which might otherwise be considered severe, less unfavourable, especially quickness of pulse and heat of skin. —(*b.*) A *weak* respiration is characterised by the slightness of the motion of the respiratory apparatus, and by the diminished action of the respiratory muscles. It is a fatal symptom in pulmonary maladies, and in low or nervous fevers. It is chiefly in syncope or faintness, and in catalepsy, in which it is commonly the most remarkable, that it is of the least prognostic importance. — (*c.*) A *full* respiration is generally present in healthy persons during exercise, or in excited states of nervous power and of the circulation. It is present, in varying grades, in all febrile and inflammatory affections, or in disorders of excitement unattended by diseases of the respiratory organs, and it does not indicate danger, when it is uniform, easy, and without pain or difficulty. — (*d.*) A *strong* respiration is a higher grade of the last, and always is attended by some degree of exertion. It occurs in affections of the trachea and bronchi; in congestive pneumonia, in several diseases of the heart, and in the more sthenic states of fever.

180. *e. Difficult respiration,—Dyspnœa*—is attended by much more muscular exertion than the former, and is present in asthma, in bronchitis and pneumonia of both lungs, in effusion into the pleural cavities, in obstructive and congestive diseases of the heart and large vessels, in emphysema of the lungs, &c. In this state of breathing, certain modifications may be remarked depending upon the seat and severity of the malady. — 1st. The respiration may be *abdominal*, owing to increased action of the diaphragm, and to the consequent motions of the abdomen. This is observed in apoplexy, in certain states and forms of fever, attended by cerebral congestion and exhaustion, in pleuritis, fracture of the ribs. — 2nd. The breath-

ing may be *thoracic*, the abdomen presenting but little motion; as in inflammation of the liver, or stomach, or bowels, or of the peritoneum — of the last especially; or in ascites, or enlargement of the spleen or liver; or other changes impeding or preventing the free action of the diaphragm may be present. If the breathing be both thoracic and abdominal, great difficulty of, or obstruction to, respiration manifestly exists in the organs contained in the thorax, or in the respiratory passages. — 3d. According as certain muscles are called into action during breathing, the degree of difficulty may be determined and the severity and danger of the malady inferred.

181. The more that the action of the upper ribs co-operates in enlarging the thorax — the more high the thoracic movements are observed — the *respiratio sublimis* — the more difficult is the breathing and the more dangerous is the malady, as in hydro-thorax, the advanced states of diseases of the heart and pericardium, in bronchitis of both lungs with mucous accumulations, in congestive pneumonia, in tracheitis, &c. In the more extreme cases of this kind, but chiefly in croup, laryngitis, œdema of the glottis, &c., the muscles of the neck are also brought into action, and the muscles also of the face are often also sympathetically affected. In the maladies just now mentioned the motions of the thyroid cartilage upwards and downwards with each forced expiration and inspiration are extensive and remarkable. When the motions extend to the mouth and nostrils, in difficult respiration, the danger is extreme. The act of inspiration is most difficult, from its commencement, in the several states of croup, laryngitis, inflammation of the epiglottis, in laryngismus stridulus, and in all affections of the glottis: it is most difficult towards the termination when the disease is seated within the thoracic cavity. In some cases of difficult respiration, the patient can take a deep and full inspiration, and yet he breathes with difficulty and frequently. In these the heart or brain, or some other organ, but not the lungs, is affected. In bronchitis, in tubercular consumption, in asthma, and in emphysema of the lungs, expiration is often more difficult than inspiration.

182. In the acute diseases of the thoracic organs, the degree of dyspnœa is not always proportionate to the severity of the attack, or to the amount of organic change. But in all acute cases, a laboured respiration is always unfavourable, especially when it is continued. And, in chronic affections of these organs, a gradually increasing dyspnœa, without remission, is even still more unfavourable. Dyspnœa is always greatest when both lungs are affected; and when it is consequent upon the retrocession or disappearance of acute eruptions, especially in the exanthemata, it is always a dangerous sign. If the dyspnœa be attended by profound debility, or lividity of the lips, or gums, fingers, &c., death is near.

183. *f. The Sensations experienced during respiration* are most important. These are chiefly pain, anxiety, a sense of strangulation or suffocation, and a feeling of impending dissolution. — *Pain* is felt, chiefly during inspiration and towards the close of the act, in pneumonia, in pleuro-pneumonia, in pleuritis, &c., and at the commencement of the act in pleurodynia, acute pleurisy, peritonitis, &c. If it be experienced only when taking a full respiration, adhesions of the lungs to the costal pleura are probably present; but inflammatory action may, in those cases, exist in the lungs, or even in other organs, according to the seat of pain, when thus excited. In bronchitis, bronchial catarrhs, and influenza, the pain is often felt most, at the advanced stage, or towards the termination, of the act of expiration. *Pain* in one or other of the regions of the chest may be constant, but more or less aggravated during respiration, or it may be experienced only during this act, or not be felt unless the inspiration or expiration be full and deep. Pains about or below the collar bones, shoulders, shoulder-blades, in the back, or between the shoulders, are frequent in tubercular consumption, and may exist independently of inspiration, although often increased by it. When thus increased and experienced towards either side of the sternum or towards the angles of the ribs, or even in the back, chronic adhesions exist, or are being formed, between a portion of lung and the ribs. Pain in the sternum, not aggravated by full respiration, is often syphilitic; if aggravated or caused by respiration, especially expiration, it is produced by bronchitis, or inflammation of the mediastinum. Pain, in the cardiac region, if it be continued, but aggravated by breathing fully, or if it extends to the left shoulder and arm, may depend upon carditis, pericarditis, or endocarditis, more especially if rheumatism of some joint or part have preceded it, or accompany it. If the pain continue in the same part, it indicates acute or chronic inflammation of the subjacent structures. If the pain shift about it may be owing to hepatic congestion, or to some other biliary disorder, or to rheumatism or pleurodynia. Pain in the right shoulder, and under the right shoulder-blade, is generally caused by disease of the liver. When pain is increased by pressure it may be attributed to pleurodynia, or pleuritis, or to pericarditis. The motions of the arm and chest increase the pain of pleurodynia. A dull pain, a feeling of weight or oppression, or tension, attends pneumonia, congestion of the lungs or heart, dropsy of the thoracic cavities, and enlargements of the liver or spleen, especially when great, and in certain positions of the body. Intensity of pain is seldom proportionate to the severity of the disease of the thoracic viscera. It is generally greatest or most acute when the attack is sudden, extensive, and seated chiefly in the serous tissues. In most cases when the pain is increased, or is induced, by full respiration, there is more or less anxiety.

184. *g. Anxious* respiration is most frequent during congestive states of the lungs, heart, large blood-vessels, and brain; but more especially in diaphragmitis, pleuritis, in disease of the valves or orifices of the heart, in fatty softening of the substance of this organ; and towards the fatal termination of inflammations of the lungs, bronchi or pleura, and of thoracic dropsy. It is always an unfavourable symptom. — A *strangulating* or suffocative respiration occurs chiefly in croup, laryngitis and other affections of the larynx or trachea. — Respiration may be attended by a feeling of impending *dissolution*, especially when it is frequent, short and difficult, especially in angina pectoris, in the organic lesions of the heart, &c., in some cases of spinal paralysis, in all which it is a very unfavourable symptom. If the feeling be caused by the

accession of syncope, the prognosis is very different, unless the syncope proceed from disease of the heart.

185. *h. Other phenomena* are presented by the breathing that deserve notice.—When the respiration is healthy it is not attended by any sound, which can be heard by the ear, when removed from the chest; but in cases of difficulty, especially in the states now described, various modifications of *sound* may be heard. The sounds of inspirations and expirations become audible and even somewhat loud, during or after physical exertion, especially ascending eminences, and at the same time frequent, strong and deep. Respiration is *suspirious* or sighing, during states of mental anxiety and depression, of pulmonary, and of cardiac congestion, in cases of nervous depression or exhaustion, in hysteria and in hypochondriasis, and in hepatic or biliary congestion. Recovery from faintings, syncope, hysterical paroxysms, and from catalepsy, is attended by suspirious breathing.—A *panting* or *gasping* respiration is observed chiefly in the most extreme or dangerous cases of thoracic disease, and in the same circumstances as have been noticed in connection with the most difficult states of respiration, of which this is the most fatal. It often terminates life in cases of pneumonia or of bronchitis, or of congestion of both lungs, in the advanced states of organic disease of the heart, of hydro-thorax and hydro-pericarditis, and in diseases of the larynx and trachea. In these last, in asthma, in œdema of the glottis, and in hysterical affections of the throat and neck, the breathing is often also suffocative or strangulating, and attended by a *sibillous*, or *hissing* sound. In the spasmodic states of the larynx, as in laryngismus stridulus and hooping-cough, the sound is *crowing*, *loud*, and *stridulous* at each inspiration, ultimately ceasing in a short time, or becoming strangulating and suffocative, and terminating life with the usual phenomena of asphyxia. —As to the sounds of respiration in the several regions of the chest, on AUSCULTATION, I must refer the reader to that head.

186. *i. States of the expired air in respect of temperature and odour.*—*A.* The *temperature* of the expired air is always more or less above natural in sthenic inflammations of the lungs, bronchi and pleura, during inflammatory fevers, and in the state of vascular excitement in continued and periodic fevers. It is slightly lower than in health in states of vital depression, especially in congestive affections of the thoracic organs, and in disorders of debility; and it is much lower in the last or the advanced periods of fevers, particularly the adynamic, the typhoid and the malignant, and in the asthenic forms of the exanthemata. It is lower still, being almost cold and raw, in the choleric pestilence, and in the extreme or fatal states of congestion, when the changes produced by the air on the blood cease, or nearly cease to take place.

187. *B.* The *odour* of the breath varies much. In perfect health it is sweet or pleasant; but during disorders of the digestive organs, it is foul, loaded or unpleasant. It is more or less unpleasant, in cases of dyspepsia, during flatulence and costiveness, and during the catamenia, when the odour is peculiar. It may be rendered very unpleasant by several articles even during health, as by eating onions, leeks, assafœtida, garlick, &c. The odour of the breath of those attacked by continued, exanthematous, malignant, and pestilential fevers, is most unpleasant and infectious, especially to the predisposed. In those the odour is particularly disagreeable; and the humidity of the expired air is often unusually great, and loaded with animal matter, especially at an advanced period of these maladies, as shown by breathing on a mirror or on any cold polished surface.

188. A disagreeable odour of the breath is present also in scurvy; in cancerous diseases of the stomach, mouth, uterus, &c.; in malignant sore throat; in gangrene of the lungs; in constipation of the bowels, and frequently in diarrhœa, especially in the diarrhœa precursory of pestilential cholera, and in asthenic dysentery. In this last and in chronic diarrhœa, an earthy or cadaverous odour of the breath is a most dangerous sign. In verminous complaints and in chlorosis the odour is sweetish or resembles that of new milk.—There are several other topics connected with respiration, but certain of them have received a special notice under their respective heads, as COUGH, HICCUP, VOICE and SPEECH, and to those the reader is referred. It therefore only remains to consider at the place the *Expectoration* and the *Signs connected with Expectorating.*—

189. ii. THE EXPECTORATION furnishes much information as to the nature, seat and issue of disease; especially of pulmonary diseases.—It may consist —1st. of morbid mucus;—2d. of purulent mucus; —3d. of purulent mucus containing portions of tubercular matter:—4th. of pus or ichorous matter; —5th. of blood, or blood conjoined with either of the preceding; — 6th. of fibrinous substances moulded in the bronchi; and 7th. of calcareous matter, or hard concretions formed in, or the remains of tubercular deposits.— In order to form a correct idea of the various matters thrown off the respiratory passages, the appearance and composition of healthy mucus from these passages should be noticed. There is, however, much difficulty in obtaining healthy mucus from these sources, as it is more or less altered from the normal state when excreted in such quantity as admits of its examination, and it is so mixed with the secretion of the bronchial glands, and so changed by the air, and the states of the air in certain localities, as to modify its condition very remarkably. The mucus of the bronchi is propelled along these canals by the ciliary motion on the surface of the mucous membrane, and by the respiratory functions. The mucus excreted is a viscid, tough and tenacious or stringy matter, which is often clear or colourless, but more frequently it is turbid, of a grayish, or faint yellowish white tint, and of semi-fluid consistence. According to SIMON it consists, chemically, of a varying proportion of water and of the following constituents, namely, mucus-corpuscles, epithelium cells, mucin, small quantities of extractive matters and fat, chlorides of potassium and sodium, alkaline lactates, a little carbonate of soda and phosphate of lime, and sometimes a minute quantity of albumen.

190. *A. Morbid Mucus* is produced chiefly by catarrh, bronchorrhœa, and by bronchitis; and in these especially, as well as in several other diseases, it is often produced in great quantity, and in various states.—The quantity, as well as the appearances, of the pulmonary sputa depends much

upon the quantity of water or serum, and of albumen, with the other ingredients just mentioned. The sputa are most watery or serous in bronchorrhœa, and in congestive and œdematous affections of the lungs: they are most viscid and albuminous in the inflammatory states of the bronchi. In these states the sputa are whitish, or of a pale yellow colour, and float in water. They possess a certain degree of consistency, and feel slimy in consequence of the mucin connecting the mucus-corpuscles.

191. *B. Purulent Mucus* from the lungs contains much less mucin than normal and morbid mucus; and consequently the sputa have not the toughness, lubricity and consistence of mucus unmixed with pus; and have a decided tendency to dissolve. In bronchitis and other affections of the lungs, the transition from morbid mucus to purulent mucus is so slight, that it is hardly possible to detect the first traces of pus mingled with the mucus — or to determine the presence of a little pus in mucus, or of a little mucus in pus. Purulent mucus sinks more quickly in water, than the healthy secretion, owing partly to its containing less air, and partly owing to the greater quantity of albumen and of chlorides and higher specific gravity. Equal proportions of mucus and pus readily sink in water. A small amount of pus separates from the mucus when placed in water. Phthisical sputa, which commonly consist of purulent mucus, deposit a whitish granular sediment at the bottom of the vessel, while masses of mucus are still floating on the surface of the water.

192. *C. Purulent Mucus with softened tubercular matter* is observed in the second and third stages of phthisis. Most of the expectoration in the malady proceeds from the chronic bronchitis which accompanies it. When the sputa is placed in a glass vessel containing water, then minute portions of softened tubercle, or much larger fragments may be detected either adhering to the mucus, or sunk to the bottom of the vessel with the granular sediment consisting chiefly of the purulent portion of the excretion. These fragments of softened tubercle consist either of whitish streaks, or yellowish white masses, resembling portions of boiled rice, or of greenish white matters, of irregular shapes. (See Art. Tubercular Consumption.)

193. *D. Pus and Ichorous matter.*— *a.* Pus may proceed from three sources: — 1st. from violent inflammatory irritation of the bronchi. — 2d. from inflammation of the parenchyma of the lungs, — or 3d. from a vomica or abscess opening into the bronchi. This last is comparatively rare; and pure pus is very seldom produced by the first and second sources. Violent irritation of the respiratory passages may cause the formation of pus in place of the mucous secretion. Hence the production of pus is owing to a greater intensity of the same morbid action which, in progressive grades, produced morbid mucus and purulent mucus: — but it may be assumed that even in this highest grade a small proportion of mucus may still be present. Genuine pus is a somewhat thick fluid, viscid, but capable of separating in drops, like cream, of a whitish-yellow, yellow, or greenish-yellow colour; and of a faint animal odour. It may be slightly acid, or slightly alkaline, or even neutral. When mixed with water it soon sinks to the bottom, and on stirring it forms an emulsive fluid from which a sediment of pus-corpuscles is soon deposited. When examined under the microscope, pus appears, like mucus, to consist of a clear fluid in which small, round, and occasionally oval corpuscles are swimming, the quantity of which is in a ratio with the thickness of the pus. Pus and mucus-corpuscles closely resemble each other in form and chemical relations. Their sizes are nearly the same; but the nuclei of the former become more distinct than those of the latter when the corpuscles are treated with acetic acid.

194. The *liquor puris*, or fluid in which the corpuscles are contained, is transparent, and usually of a pale yellow colour. It contains so large an amount of albumen, that on the application of heat it becomes white, and very flocculent. The large amount of albumen, and of the chlorides, especially the chloride of sodium, associated with a small quantity of fat, distinguishes the fluid portion of pus from the consistent and adhesive fluid of mucus, and indicates the affinity between the liquor puris and lymph. The fat is chiefly contained in the pus-corpuscles, the nuclei probably containing a large proportion of it. In the liquor puris the fat is combined with alkalies.

195. It appears from the researches of Gruby, Simon, and others that pus consists of two distinct portions:— 1st, A fluid, or liquor puris:— 2nd, And of corpuscles swimming in this fluid, and insoluble in it. The corpuscles are surrounded by a capsule which becomes tumid in water, is soluble in free potash and is reduced by ammonia to a thick viscid jelly, dissolves on prolonged gentle digestion, and is doubtless composed of mucin. Of the nature of the contents of the corpuscles lying between the nucleus and the capsule nothing is known. The nucleus probably consists of albuminous matter and fat. The liquor puris contains much albumen, some fat, pyin or dissolved mucin, extractive matter and salts. In pneumonia, as the chlorides, especially the chloride of sodium, are increased in the sputa, they are diminished, or disappear in the urine.

196. An *ichorous matter* is sometimes expectorated when gangrene of a portion of the lung takes place, and in malignant growths in the lungs. It may either proceed from a decay or other change of pus, or be secreted from the gangrenous or malignant part. This matter is thin, discoloured, of a brownish or reddish tint, and emits a fetid odour. It often either contains no pus globules, or very few; and those are broken down. Although ichor is of a reddish colour, it may not contain blood corpuscles; these corpuscles having been dissolved in the morbid fluid, and having thereby imparted this colour to it. Mucus, or muco-puriform matter, may be expectorated with it in greater or less proportion, owing to the irritation of the bronchial membrane over which it passes during the process of its excretion. The presence of this matter is always indicative of great danger. Recovery may, however, take place when it proceeds from gangrene of a small or isolated portion of the lung.

197. *E.* Blood may be present in any of the states of the sputa already described. It may form, in a pure and unmixed state, the whole or the chief amount of the expectorated matter, or accompany more or less of either of the preceding kinds. It

may merely streak or dot the sputum, or be so intimately mixed with it as to give it a pinkish, reddish, rusty or brownish hue. When the blood is at all considerable, it proceeds from one or other of the sources described when treating of HÆMORRHAGE from the respiratory organs: it may be caused by interrupted circulation through the heart, or by congestion of this organ, or by congestion of the lungs and bronchi, with or without congestion of the heart, or by the irritation or congestion produced by tubercles, or by inflammatory action, or by the ulceration or erosion of vessels in tubercular cavities, or by disease of the coats of the capillaries or arterial ramifications. It was the fashion, formerly, to ascribe all hæmorrhages from mucous or villous surfaces to an exudation from the capillaries of these surfaces; but this, although a common source, especially when congestion or inflammatory irritation exists, does not always or even generally obtain, for ulceration or erosion of vessels, and disease of their coats, especially suetty or atheromatous deposits in them, favouring their rupture when congested, are not infrequent sources of hæmorrhage, especially when the discharge of blood is large or very considerable. When the bloody expectoration is small in quantity, it commonly proceeds from exudation, owing either to congestion and relaxation of the capillaries, and then it is rusty or dark-coloured, as in congestive or asthenic pneumonia, or to inflammatory irritation of the bronchi adjoining the inflamed portion of lung, and then the blood is of a more florid red, in very small quantities, and mixed with a muco-purulent matter, as in sthenic pneumonia and in tubercular consumption.

198. When blood has been expectorated in either large or small quantities, it often continues to colour the sputa for several days afterwards, the colour generally passing from a dark red to a brown, or rusty, to an ochry and greenish hue, as the quantity of colouring globules diminishes or becomes altered in the containing fluid. Extravasated blood always occasions more or less irritation in the mucous surfaces over which it passes, and hence a more copious expectoration of morbid mucus or of muco-purulent matter follows the hæmorrhage, and continues for a longer or shorter period, according to the nature of the primary and consecutive changes. When blood is present in the expectoration in a quantity merely sufficient to colour the expectoration, and is intimately mixed with it, pneumonia is certainly present, the variation of the tint from red to brown, or from a reddish brown to that of prune juice, indicating the failure of vital power. If the blood merely appears in minute streaks or spots, severe catarrh or bronchitis may only exist; but if it occur in larger spots or patches, pneumonia or phthisis is commonly present. When the spots of blood are found in a copious turbid or muco-purulent expectoration, then phthisis or very severe bronchitis exists. When they are seen in thick yellowish or greenish-yellow and rounded sputa, then pneumonia may be inferred: in these cases the prognosis is very unfavourable. A frothy, fluid and bright red blood is usually an exudation from the bronchial membrane in phthisis. Dark-coloured blood, without froth, and without muco-purulent expectoration, and in large or considerable quantity, proceeds generally from congestion, or from erosion of vessels in a tubercular cavity, or from pulmonary apoplexy. Clear fluid blood, without froth, and in large quantity, comes either from aneurisms, or from eroded or diseased vessels.

199. The bleeding may proceed from the pharynx, or even from the posterior nares, and, owing to the irritation produced by it in the glottis or epiglottis, occasion a hawking cough; but in these cases, redness is generally observed in the throat. The bleeding may be vicarious of menstruation, or of hæmorrhoids, or be consequent upon the suppression of either; and if in these cases there have been no antecedent symptoms of phthisis, the blood may proceed chiefly from the bronchial surface; but, even in these, it is often followed by, or connected with, either bronchitis or tubercular deposits. When the bloody sputa occur in fevers, and in the course of cardiac disease, the prognosis should be very unfavourable: it may be less so when bloody sputa are observed in scurvy and purpura. In all these cases numerous concomitant and antecedent circumstances should be taken into consideration.

200. *F.* FIBRINOUS EXUDATIONS take place, in rare cases, in chronic and in sub-acute states of bronchitis, and are moulded in the ramifications of the bronchi. They are generally expectorated in the form of the bronchial tubes, and present various extents of ramification and degrees of firmness and tenacity. These ramifications are very rarely hollow: they are commonly either filled with a softer matter, or are firmer in the more external layer. They resemble the false membranes or fibrinous exudations formed in the larynx and trachea in croup: and which are frequently thrown off in that disease accompanied with more or less gelatinous or glutinous mucus. (See Art. BRONCHI, § 49. and CROUP, § 33.)

201. *G.* EARTHY OR CALCAREOUS CONCRETIONS are sometimes expectorated by persons who have had phthisical symptoms and recovered, or who are still suffering them in a chronic form, or have suffered in various grades for several years. I have seen many of these cases. These concretions vary in size from that of a head of a pin, to that of a small bean. Their surfaces are generally unequal, irregular and ragged. The expectoration of them may or may not be attended by much sputa, which may or may not be coloured with blood: most frequently the sputa are scanty, and are only minutely streaked or dotted with blood. A medical man called upon me, complaining that on each inspiration and expiration, but during the latter especially, there was a loud whistle, which could be heard at any distance in the room from him. He had neither cough nor expectoration; and he stated that he had not experienced either for several years. He was a fluent and eloquent speaker and lecturer, and never experienced any inconvenience from speaking for a long time; but many years ago, he had had some pulmonary symptoms. I told him that one of these concretions, of considerable size, was making its way through the parietes of one of the large bronchi, and that he would expectorate it in the course of a few days. He did so; the concretion being the size of a large pea. He is quite well at this time. A relative of my own has expectorated many of them, at different periods, the largest being the size of a small bean. She has been the subject of chronic phthisis for many years; but is now able to be about, and go out of doors.

202. *H.* The Expectoration in the several forms of disease of the Respiratory Organs has been fully described under the separate heads of Catarrh, Cough, Bronchi, the diseases of, Hæmorrhage *from the respiratory organs,* Lungs, the diseases of, Pleura, Tubercular Consumption, &c.; but it will, nevertheless, be useful to give at this place a brief *resumé* of the appearances of the sputum, in those maladies, in which it is present in increased quantity or altered quality. — (*a.*) In *dry catarrh* the sputa are scanty, and consist of small pellets of tough, greyish or greyish-yellow mucus, which are expectorated after severe fits of cough. — (*b.*) In *pituitous catarrh,* the sputa are much more abundant, and thin or watery, consisting of a serous mucus, containing albumen and mucin. This expectoration varies much in quantity and appearances, with the severity of attack, the congested state of the lungs, and with its complication with rheumatic or cardiac affections. — (*c.*) In *broncorrhœa* the expectoration is watery or serous, most abundant, and sometimes extremely so when complicated with pulmonary congestion or cardiac disease. — (*d.*) In *acute bronchitis,* little or no expectoration occurs at first: but a liquid, slightly saltish sputum is soon formed, which gradually increases with the progress of inflammation. It is at first transparent, nearly colourless, moderately viscid, retains many small air bubbles, and is frothy on the surface, especially when expectorated after much coughing. When expectorated in the same vessel, the sputa coalesce, and may be drawn into a ropy stream. The viscidity of the sputa is in proportion to the severity of the inflammation, of the fever, and of the dyspnœa. As the disease declines, the sputa become pearly, opaque, or of a yellowish or greenish white, and more consistent and glutinous. If a relapse or exacerbation takes place, the expectoration becomes thinner, more transparent, glairy, and frothy. As amendment advances, the sputa are more readily coughed up, and in more distinct pellets, which do not so readily unite into one mass as before. They gradually diminish in quantity. — (*e.*) In *chronic bronchitis* the sputa vary much in different cases, and in the same case at different periods. They are frequently similar to the sputa at an advanced period of the acute form. They are often opaque, yellowish or greenish-white, owing to an admixture of a muco-purulent matter of this hue, with mucus, and a watery or serous fluid. Sometimes the thick, opaque matter floats in the pituitous or serous fluid expectorated with it. In other cases, the mucus is inspissated, fibrinous, and moulded into the shape of the bronchial ramifications (§ 200.).

203. (*f.*) In *pneumonia,* the sputa, after the first two days, consist of a viscid, transparent fluid, tinged with an orange or rusty hue. At first they resemble the sputa of acute bronchitis, and they may be poured from one vessel into another in the form of viscid strings. At a more advanced stage, the sputa become so glutinous and viscid as not to leave the vessel even when inverted. They are, also, more streaked with blood, or red, or rusty. As the disease declines, the sputa assume the first or bronchitic appearance. In unfavourable cases, the expectoration becomes more viscous, more rusty, brown, opaque, or purulent. In some still more unfavourable cases it is altogether suppressed, owing to its viscous nature, and the want of power to throw it off; suffocation taking place, with lividity of the prolalabia and extremities. In other unfavourable cases, the expectoration assumes the form of a deep, reddish-brown and slightly viscid liquid, like the juice of preserved prunes or liquorice water. This appearance indicates the existence of suppuration, or of a cachectic state of inflammation which has gone on to softening or purulent infiltration. The characteristic sputa of pneumonia, or pleuro-pneumonia, are orange, greenish-yellow, reddish, bright-red, or streaked or dotted with red, or rust-coloured, according to the amount of red globules contained in them. — (*g.*) In *pleurisy,* the expectoration is scanty, mucous, or muco-serous, or resembles that in the different forms of catarrh.

204. (*h.*) In *phthisis,* the expectoration is varied according to the stages of the disease, and is chiefly from the bronchi during the whole course of the malady, and altogether from them during the first and second stages. In some states of phthisis little or no expectoration takes place throughout, or not until shortly before death. In the *first* stage there is either no expectoration, the cough being dry, or it is of a simple catarrhal or bronchitic character, or sero-mucous, and more or less abundant, especially when the lungs are thickly studded with tubercles, a mucous rhonchus being generally heard on auscultation. In the *second* stage, the expectoration continues as in the first, or assumes a more bronchitic character, or passes into the muco-purulent form of chronic bronchitis, until the softening and evacuation of the tubercular deposits. When the softened tubercles make their way into the bronchi, the irritation of these canals is increased, the mucous or muco-purulent expectoration is augmented, and contains whitish streaks, or whitish-yellow fragments, consisting of the softened tubercles. As the softening and formation of a cavity proceeds, the sputa assume further changes, which have been already noticed above (§ 192.), or fully described in the article on Tubercular Consumption.

205. (*i.*) The sputa are *evacuated* or *expectorated* with various degrees of ease or of difficulty, according to the nature and stage of the disease, the state of the sputa, the age and the strength of the patient. They may be hawked up, with much ease, in some cases, or coughed up, with more or less difficulty, in others. They may be expectorated and swallowed, as in children, and sometimes in adults, when they are not very abundant. The rapid, violent, and loud expiration, by which expectoration is generally effected, and cough produced, is caused by irritation existing in, or sympathetically propagated to, the larynx. *Cough* may thus be occasioned either by the irritation of sputa, when they reach the larynx, or sympathetically by disease in any part of the respiratory apparatus, or by disorders of the stomach, œsophagus, or pharynx and fauces. In the former case, expectoration follows the cough; in the latter, there is no sputum, or very little. (See Art. Cough.) The more viscous the sputum, the more difficult is the cough, especially in bronchitis; the cough often becoming suffocating or even strangulating as the sputum passes the larynx, as in croup, and the bronchitis of old persons, especially at a far advanced stage. As the strength of the patient sinks, the morbid secretion accumulates, is expec-

torated with greater difficulty, sometimes becomes more viscous, and hence still more difficult of discharge, the functions of the lungs are impeded, and ultimately arrested.

206. iii. YAWNING and SIGHING are nearly related phenomena, both consisting of prolonged inspirations, and both indicating nervous weariness or exhaustion; or the depression depending upon mental longings, fatigue, or approaching sleep. They are often present during the more slight states of congestion of the lungs, or heart, or large vessels; and they are generally of service in relieving these states, by accelerating the circulation, and by more fully dilating and supplying the air-cells with fresh air. They are frequently observed during the premonitory and invading stages of acute or febrile diseases, and in states of nervous exhaustion, and general debility. Whilst yawning is most frequently a sign of *ennui*, or of mental vacuity and fatigue, sighing is most commonly a sign of mental depression, melancholia, or hysteria.

207. iv. SNEEZING is a reflex, spasmodic action of the respiratory muscles, consequent upon irritation or titillation of the Schneiderian membrane. It consists of a deep inspiration followed by a sudden and violent expiration, by which the air is driven out through the nose and mouth with much force and an audible noise. It is most commonly occasioned by an incipient catarrh; but it may occur from various causes of irritation implicating the nasal and respiratory passages, and as a sympathetic phenomenon in hysteria and in verminous disorders. It sometimes, when frequently repeated, precedes or ushers in an attack of apoplexy or palsy.

208. Of *Laughing* and *Weeping*, it is unnecessary to remark further, at this place, than that they are chiefly manifestations of certain opposite states of mental emotion; that they occur chiefly in susceptible, and often weak minds; and that they are characteristic phenomena of the hysterical paroxysm. They are sometimes of use, the latter especially, in moderating the emotions; laughing, by its mechanical stimulus, or its successions, transmitted to the biliary apparatus; weeping, by proving a serviceable derivation from a congested brain, or an overloaded or congested heart and large vessels.

209. VI. SYMPTOMS AND SIGNS CONNECTED WITH THE URINARY AND SEXUAL ORGANS. — The signs furnished by the urinary and sexual functions and organs are of the greatest importance, as respects not only the diseases of these and of related organs, but also numerous maladies of distant parts and of the whole frame. Those signs which more immediately belong to diseases of these organs, are described in the articles upon these diseases, especially in those treating of the KIDNEY, of LEUCORRHŒA, of the OVARIA, of the URINE, URINARY BLADDER and PASSAGES, of the UTERUS and VAGINA, and of the VULVA.

210. i. THE SIGNS FURNISHED BY THE URINARY EXCRETION. — The signs connected with the urinary functions divide themselves into — 1st, those which are connected with the chemical and physical states of the *Urine* itself, — and 2d, those which depend upon the modes of *excreting* the urine. The *first* of these are discussed in the article URINE, and several of both the first and *second* are directly dependent on diseases of the URINARY ORGANS. Both orders of signs may appertain either to diseases of these organs, or to diseases of the brain or spinal chord, or to maladies implicating the whole frame, as pestilential, malignant, or exanthematous fevers; or to disorders of the digestive, assimilative, the excreting, and the sexual organs. The great interest which thus necessarily attaches itself to states of the urine, and of the excretion of it, will become at once apparent, from the connections just enumerated. Reserving, however, the chief topics connected with these subjects for the articles just mentioned, I shall merely glance, at this place, to a few of those which are of less importance, and which are signs merely of disorders of distant organs, or of constitutional maladies. Of the states, changes, and chemical conditions of the urine, I have treated at another place (see Art. URINE): I now notice merely changes in the function of excreting it.

211. *A. The excretion of the Urine* may become difficult, painful, changed, or arrested; and the *secretion* of it may be scanty, or altogether suppressed, the excretion being similarly affected. Difficult excretion of urine may amount to what has been termed *dysuria*, in a lesser grade, and to *stranguria* in its higher grade: the former requiring much effort to empty the bladder, the latter strong efforts to discharge the urine, and chiefly by drops or small quantities. *Ischuria* has been used to express the suppression or the retention of urine — *ischuria renalis*, when none is secreted, and *ischuria ureterica*, or *vesicalis*, or *urethralis*, according to the seat of obstruction. — *a*. Dysury and stranguary may proceed — 1st, from diseases of the urinary organs and passages: — 2d, from the conditions of the urine itself, or from the presence of a calculus or calculi in the bladder or urinary passages: — and 3d, from disease of either adjoining or distant viscera, as in cases of dysentery, of hepatic or splenic disease, or of uterine or ovarian lesions. Neither dysury nor strangury should be viewed as devoid of risk, whenever observed. If either occur in aged persons, or in those who have previously experienced disease of the urinary organs or passages, a most minute examination should be instituted to ascertain the nature and seat of lesion, from which alone the amount of risk or danger should be inferred.

212. *b. Ischuria* may more correctly be divided into that of *suppression*, and that of *retention*. The *suppression* or non-secretion of urine is caused 1st, by inflammation or structural changes of the kidneys themselves: — 2d, by congestions, inflammations, or other alterations occurring in the course of exanthematous or other fevers, or pestilences: — 3d, by organic or other maladies of the brain, spinal marrow, or their membranes. In all these circumstances, the ischuria is a most dangerous sign, inasmuch as it consists of the suppression of a function by which the principal part of the injurious, effete, and irritating materials accumulating in the blood is eliminated and discharged; the arrest of the function being necessarily followed by very manifest alterations of the blood, by an uncommon excrementitious plethora, and by effusions in shut cavities and cellular parts, by coma and death, unless restoration of the excretion take place before these results have reached an irremediable extent. The *ischuria suppressionis*, in the three classes of disease in which it occurs, is nearly equally dangerous; as respects the general results, it is least so in inflammation or congestion of the kidneys; it is most dangerous, or commonly

fatal, in diseases of the brain and spinal chord, and it is not much less dangerous when it occurs as a complication of exanthematous or other fevers or pestilences. In scarlet fever, the kidneys are often asthenically inflamed or congested to an extent incompatible with the performance of their functions, the excrementitious matters and fluid which should be excreted by them thereby accumulating in the blood. In pestilential cholera, the ischuria is a consequence of the excremential fluid of the blood being all discharged by the digestive canal and skin, none being left that can be removed by the kidneys; other excremential matters, however, accumulating in the blood, owing to the suppression of the renal function, and consecutively inducing secondary fever and fatal complications.

213. *c. Ischuria retentionis* — the ischuria of retention, or of obstruction, — may take place either in consequence of an obstruction at the outlet of the pelvis of one or both kidneys, or in the course of the ureter, by a calculus, tumour, or any other lesion, or by inflammation, suppuration, &c., implicating either or both these. In all these cases the urine may be secreted, may accumulate in the pelvis of the kidneys or ureters above the seat of obstruction, and none may reach the bladder. But the *ischuria of retention* most frequently occurs in consequence, 1st, of *paralysis* of the coats of the bladder, consequent upon disease or injury of the brain, spinal chord, or their membranes; or of congestion of the nervous centres and paralysis of the bladder, in the course of typhus or low fevers; — and 2d, of *obstruction* to the discharge of urine from the bladder, sometimes caused by spasm, but more frequently by disease near to, or in the neck of, the bladder or urethra, as diseased prostate, impermeable stricture, the impaction of a calculus, &c. In all these circumstances ischuria is attended by more or less danger, but the amount of danger altogether depends upon the exact nature and seat of lesion, in respect of the urinary passages, upon the age and sex of the patient, and the progress and duration of the pathological lesion by which the ischuria is caused.

214. *d.* Ischuria may occur, however, in hysterical females — *Ischuria Hysterica* — and may depend upon either congestion of the spinal chord, and paralysis of the bladder, or upon spasm of the cervix vesicæ; most probably upon the former. Several cases of this form of ischuria have come under my notice, in which the urine required to be drawn off, twice or thrice daily, yet complete recovery has ultimately taken place. It is generally caused by masturbation, and is sometimes feigned.

215. *B. Inability to retain the Urine — Incontinentia Urinæ — Enuresis,* occurs in various forms. It may follow ischuria, or may take place even in connection with over-distension of the bladder; the coats of this viscus having been so over-distended as to have lost the power of contraction and of evacuation. In this case, there is a constant dribbling of the urine. In such cases the prognosis is unfavourable, and especially in aged persons. The incontinence may proceed from the state of the urine itself, especially when, owing to disease of the kidneys, it contains either blood or albumen: but this form consists rather of frequent calls to pass urine, the quantity being small, than of absolute incontinence. Very frequent calls to micturate occur in most inflammatory diseases of the urinary organs, and more especially in those affecting the bladder. In such cases, these calls take place as soon as a spoonful accumulates in this receptacle. This incontinence may also proceed from ulceration of the inner surface of the bladder, or from disease of the neck of the viscus, or from calculi, or clots of blood, or from foreign bodies, in the bladder, or from paralysis of the neck of the bladder. The paralytic state is most frequent in aged persons, in those who have previously suffered diseases of the urinary organs, as a consequence of strangury or ischuria, or of disease of the spinal chord or its membranes, and as a complication of typhus or of low fevers; in all which circumstances it is a very dangerous symptom.

216. *C. Frequent calls* to pass urine, more or less being passed on each occasion, sometimes occur in nervous persons, especially during states of mental anxiety or expectation; and in hysterical females. In many instances, the quantity of pale urine passed on one, or on several occasions, in connection with hysteria, is often surprising. In these, this symptom need not create much anxiety; but in all cases of frequent calls to micturate, especially during night, the urine ought to be tested, in order to ascertain the presence of albumen, or other substances, in it. Whenever this complaint occurs, the state of the urinary organs and the habits require attention, and should be ascertained in connection with the physical state, the quantity, and the chemical condition of the urine itself, and with the functions of the digestive and circulating organs.

217. *D. An external examination of the abdomen* should always follow the recognition of the symptoms and signs connected with the urinary organs and urine. Percussion will aid in ascertaining the existence of enlargement of the kidney, or of distension of the bladder. Increased size of the kidney, or the accumulation of fluid in the pelvis of the organ, may be inferred, when, with marked dulness on percussion, there is also a fulness or tumour felt, whilst the region between the lower ribs and margin of the ilium is pressed forwards, the thumb being gently moved or pressed anteriorly. But the bowels ought to have been freely evacuated before this examination can be confided in. The *sensibility* of the region of the kidney, during this, or any other examination, affords information of great importance in determining the existence of disease of the kidney, especially inflammation and the existence of calculi in the ducts or pelvis of the organ. The ureter may be so distended in ischuria ureterica, or when a calculus is impacted in its lower extremity, as to be felt like a rope in, or closely above the inguinal region.

218. A dull sound on percussion, immediately over the pubis, indicates fulness of the bladder. Pain in this situation is a sign of over-distension; and pain behind or below the pubis is a symptom of inflammation or ulceration of the bladder, or of its cervix, and of stone in the bladder. Disease of the prostate is best ascertained by examination per anum. The existence of stricture, or stone in the bladder, &c. should be ascertained by the sound, by the catheter, bougies, &c. (*See also the Articles* Diabetes, Kidneys — *diseases of,* Prostate, Urine, and Urinary Bladder.)

219. ii. Signs and Symptoms of the Sexual

Organs.—*A. These symptoms in the Male* have not, generally, received that amount of attention which they require, as respects the states of the constitution, the diseases of particular organs, and especially those of the brain and spinal chord. The lesions to which male organs are primarily and locally liable, have been ably discussed by modern surgical and medical writers: it is chiefly as to the manner in which these organs are affected, sympathetically, in the course of other maladies, that a brief notice will be taken of them at this place. In health, the testes and penis are well developed, and the scrotum is more or less contracted; the cremaster muscles evincing sufficient tone to draw the testes close to the penis. In rare instances, one or even both testes may not have descended into the scrotum, and may have been arrested in some part of their course from the abdomen to the scrotum.

220. In *diseases* of vital depression or exhaustion, especially in fevers, in diseases of the digestive organs, and particularly of the stomach and intestines, the dartos and scrotum are no longer corrugated, the cremasters are incapable of contraction, and the testes hang down unusually low. In nephritis, and in calculus or other diseases of the kidney, the cremaster of the same side as that in which the kidney is affected is contracted, the testis drawn up close to the penis, or even to the external abdominal ring; and a darting or aching pain often is felt in the testis of that side, or extends along the chord. In those diseases in which the cremaster and scrotum are so remarkably relaxed, as just stated, the venereal desire is for the time extinguished; but with convalescence from them, especially from fevers, a restoration of the contraction of these parts, and of the sexual desire, is one of the most certain signs of recovery, as evincing a return of nervous power in both the organic and spinal nervous systems.

221. Inordinate relaxation of the cremasters and scrotum, often with more or less wasting of the testes, and sometimes with both softness and wasting, takes place in those who have prematurely or inordinately exercised their genital organs or been guilty of self-pollution. By these persons the venereal congress can no longer be either satisfactorily or fruitfully exercised. The seminal fluid is neither sufficiently nor healthily secreted, the organs being rendered incapable of discharging their functions. Hence Impotence, and one of the causes of Sterility. (*See those Articles.*) Persons who have thus destroyed their sexual functions, or who have greatly weakened them, and those who have been accustomed to sexual intercourse and who have relinquished such intercourse, are often subject to involuntary discharges during sleep, and are thereby more or less exhausted. When these involuntary pollutions are complained of, it may generally be inferred, that the individual had prematurely or inordinately addicted himself to sexual excesses, or to self-pollutions, and that having become aware of the injury they had produced, and abstained from them, the debility and morbid irritability thereby occasioned still persisting, the sympathetic excitement of a venereal dream proved sufficient to produce a seminal discharge. (See Art. Pollution.)

222. The sexual organs having been so exhausted by premature, or excessive, or unnatural use, as to give rise to impotency, and the feeling of incompetence having taken possession of an individual's mind, so as to prevent him from entering upon the married state, or from exercising these organs, the disuse actually increases the wasting, softening, or decay of these organs, and, with such decay, constitutional vigour, or vital energy, becomes impaired. A very large proportion of bachelors are actually impotent after 30 or 35 years of age, and, being conscious of their prematurely exhausted powers, prudently abstain from sacrificing the happiness of the opposite sex. All are not, however, so prudent, for some marry from various motives, although capable only of exciting a desire which they cannot gratify. Owing to the cause now noticed, the duration of life amongst bachelors is considerably less than amongst married men.

223. Loss or increase of sexual desire depending thus, 1st, upon the states of the organs concerned in the performance of the sexual functions, 2d, upon the activity or excitement of those sources of nervous energy actuating these organs, and, 3d, upon the general condition of the body, it follows, that either loss or increase of this desire becomes a symptom of disease in one or other of these quarters. It has just now been shown, that the organs destined to the performance of the sexual function may be exhausted, or altogether worn out, or disorganised, by premature or excessive use, or subsequent disease. Nevertheless the desire may exist, although performance is most imperfect, or even impossible. When this is the case, excitement is present in the sources of nervous power actuating these organs, either in the nervous centres at the origins of the nerves supplying these organs, or in the mind acting upon these centres, although these organs themselves may be incapable of discharging their offices. The excitement may be mental only — a mere passing or temporary feeling — but it may be more permanent, or even remarkable and uncontrollable; and, in this case, there is always reason to infer the existence of irritation or inflammatory action in those parts of the nervous centres — ganglial, cerebral, or spinal — most intimately related to the nerves supplying these organs. Diseases implicating the whole frame, as fevers, &c., are rarely attended by increased sexual desire, unless during convalescence from them. On the contrary, this desire is altogether abolished during their duration, whilst at the same time the sexual organs are collapsed, the testes dependant, and the scrotum flaccid and disposed to erythematous inflammation and excoriations. In acute, inflammatory, and febrile diseases, the sexual functions and desires are either impaired or abolished at their commencement, and during their continuance. In diabetes, in severe influenza, general debility, in some diseases of the brain, and in all acute maladies of the digestive canal, the sexual desire is lost.

224. The sexual desires and powers are seldom very remarkably impaired in chronic diseases of the lungs and heart, especially in tubercular consumption, and particularly in the more chronic and non-febrile states of this malady, in which they even may continue almost to the last. The same may be said of diseases of the ovaria and uterus, and, in a less degree, of chronic affections of the liver, spleen, and kidneys. Too frequent erec-

tions without sufficient cause, and seminal discharges at the commencement of, or too early in, an erection is a sign of general debility, or of susceptibility and morbid irritability of the sexual organs consequent upon masturbation or sexual abuses or upon irritation of the urethra, at the caput gallinaginis, or of stone in the bladder, or of ascarides in the rectum. But discharges from the prostate gland should be distinguished from seminal emissions, the former being much more frequent than the latter. Continued erections—*priapism*—is sometimes occasioned by calculi in the kidneys or bladder, by gonorrhœa, by epilepsy, &c.

225. *B. Signs connected with sexual organs of the Female.*— Retardation of the development of the female organs is occasioned chiefly by deficiency or atrophy of the ovaria. Want of sexual desire may proceed from the same cause, or from extreme debility, or from the same diseases as have produced his state in the male (§ 220.) Excessive sexual desire is a symptom of irritation or inflammatory action of the ovaria, or of active congestion or vascular determination to the uterus; or of masturbation, which had commenced early and been long continued. (*See further, in illustration of this subject, the Articles on* Impotence and Sterility, *on* Leucorrhœa, Menstruation, *on* Self-Pollution, *on the diseases of the* Ovaria, *of the* Uterus, Vagina, &c.)

SYNCOPE—See Fainting and Swooning.

SYPHILIS—See Venereal Disease.

TABES. — Synon.: — *Marasmus*; — *Atrophia*; *Phthisis*; — *Macies*, Auct. — These terms, as well as *tabes*, are usually employed, *generically*, to express *emaciation of the whole body with languor, and generally with some degree of hectic fever*; but to these terms are usually added certain specific appellations, according to the cause and nature of the emaciation, atrophy or tabidity, in particular cases, — as the *Tabes* or *Atrophia Infantum* or *infantilis*: — *T. Mesenterica, glandularis, scrofulosa*, &c.: — *T. Diabetica*: — *T. Lactantium* (*of Nurses*): — *T.* or *P. pulmonalis*, — *Marasmus senilis*: — *T.* or *M. dorsalis* or *dorsualis*. — *T. coxaria*; — *Tabidity, Atrophy, Emaciation, Decline.*

Classif.—IV. Class. III. Order (*Author in Preface*).

1. Defin.—*Chronic emaciation of the body, with weakness and aching of the back and loins, languor, debility, and impotency.*

2. *Tabes, Marasmus*, or *Atrophy*, is considered at sufficient length in the articles treating of the diseases, chiefly organic, on which this state, however named, actually depends. According as it proceeds from obstruction of the mesenteric glands, so it is described in the article on diseases of the Mesentery; and as arising from tubercles in the lungs or other viscera, it is treated of under the heads, Tubercular Consumption, and Scrofula and Tubercles. The other pathological conditions, of which extreme emaciation is a contingent or an occasional result merely, are so very numerous, that even an enumeration of them at this place is unnecessary, especially as they have been noticed in connection with this effect under their respective heads. But there is one form of tabes to which attention may be further directed than it has been, when treating of one of its most common causes, as well as of its usual consequences, namely, *self-pollution* and *impotence and sterility*.

3. Tabes dorsalis, in its various forms, and with its several concomitants, is of much greater

importance to the individual himself, as well as to those connected with him, than has usually been considered; and, although imputed solely to the male sex, the same affection, produced chiefly by similar causes, and characterised by nearly similar symptoms, is not infrequently also observed in the female. In the former sex it is generally *caused* by premature or excessive sexual excitement, or by consequent involuntary pollutions; in the latter it is also occasioned by the same causes, and by prolonged leucorrhœa commonly consequent upon self-pollution.

4. i. *The symptoms* in both sexes are chiefly extreme emaciation, a weak and bent state of the spinal column; the lumbar region of the spine having lost its posterior concavity, and having become either straight or convex, owing to the softened yielding or atrophied state of the intervertebral substance. The gait is unsteady and vacillating; the knees bend under the weight of the body; and all the muscular movements and mental manifestations evince debility, exhaustion, impaired powers of exertion, application and attention. The genitals are often flaccid, wasted, or soft and small, in the male; and are subject to leucorrhœa in the female; the eyes are sunk, and the whole body is emaciated. If the causes are continued, various functional and organic lesions supervene, especially nervous affections, varying in character with the peculiarities and circumstances of individual cases, hysteria, hypochondriasis, mental depression or delusion, tremors, extreme susceptibility, anæmia, and ultimately epilepsy, incomplete or complete, partial or general paralysis, insanity, and the several other consecutive maladies mentioned when treating of voluntary and involuntary POLLUTIONS.

5. ii. *The Prognosis* in Tabes dorsalis entirely depends upon the changes which the spinal chord has undergone, and upon the secondary affections which have appeared. The nature of the changes, however, which may have taken place in the chord, can be inferred with but a slight degree of certainty; for the chord may be partially softened, or it may be atrophied, or indurated, or both wasted and indurated; and the fluid existing between the spinal membranes may be increased, or the venous sinuses of the spine may be remarkably congested. The prognosis will greatly depend, not only upon the progress of the disease, but also upon the continuance of its principal cause; for, too frequently, the vice in which it has originated is persisted in, notwithstanding the conviction of the miseries which result. Although the disease may not be cured, or even much relieved, life may be prolonged for a considerable period.

6. iii. *Treatment.*—The means which have been recommended for DEBILITY, IMPOTENCY, and for POLLUTIONS, voluntary and involuntary, are altogether appropriate to this complaint, which commonly, as just stated, proceeds from the same causes as these. But unless the cause be relinquished, the means of cure may be most judiciously resorted to without avail. Of these means, chalybeate mineral waters, and preparations, change of air, and residence in a dry and temperate air, frictions and stimulating embrocations along the spine; the iodide of iron taken in the syrup of sarza; the preparations of cinchona, of gentian, of valerian, of sumbul, &c., are the most beneficial, aided by suitable diet, exercise and regimen.

CLASSIF. — 4th. *Class:* Nervous Diseases — 3d. *Order:* Spasmodic Affections (*Cullen*). — iv. *Class:* Dis. of the Nervous Function. — iii. *Order:* Affecting the Muscles, (*Good*).—II. CLASS. III. ORDER (*Author in Preface*).

1. DEFINIT.—*A tonic state of Spasm — or entonic Spasm, extending to many or to most of the muscles of animal life, or voluntary motion — with exacerbations, and usually without any period of complete relaxation, until the subsidence of the malady; its progress being generally acute or sub-acute, and often most rapid, and then terminating life by asphyxia.*

2. The *Pathology* and *Treatment* of Tetanus and Trismus have been subjects of discussion with both medical and surgical writers during many years; and even the most experienced and the ablest writers have confessed their inability to furnish satisfactory information respecting them. As tetanus is most frequently a consequence of surgical operations, and of external injuries, in temperate climates, physicians are not often called to its treatment. Nevertheless it behoves them, as much as surgeons, to be acquainted with all that

is known of both the nature and the treatment of this malady. Although it, as well as trismus, is most frequently symptomatic, yet it occasionally appears primarily or idiopathically — rarely in this climate, but not infrequently in hot climates, especially in the dark races.

3. According to its *severity* and *duration*, tetanus has been divided into *acute* and *chronic;* but in neither point of view can it be considered to be, in any case, a chronic disease. If any such division be adopted, the *acute* and *sub-acute* states may be assigned to it; but this division is altogether arbitrary; as no line of demarcation can be drawn between them. *Primary* or *idiopathic tetanus* is either acute or sub-acute, is often less violent than the symptomatic, and is less dangerous, especially in temperate climates. The *symptomatic* or *traumatic tetanus* is commonly acute and is a most dangerous malady. Besides the divisions now noticed, certain forms have been described, which are characterised by peculiar symptoms, which are merely manifestations of the disease in greater severity, or to a more limited extent in some muscles than in others. The partial state of the disease, *trismus*, is that in which the more general forms commence; the forms usually recognised being *trismus, pleurosthotonos, emprosthotonos, opisthotonos*, and *tetanus erectus;* but two or more of those forms may appear in the progress of the same case, according as the morbid action of the muscles extends or predominates in one set of muscles over the others.

4. I. DESCRIPTION.—The *symptoms* of tetanus, in all their forms, are very readily recognised; but not until those characteristic of the malady appear. Those which are *premonitory* of the attack, or which occur in the period which elapses between the cause and the declared disease, have not been satisfactorily observed. It cannot be supposed that this period is without any premonition of the impending malady. I have remarked uneasiness or pain at the epigastrium, and about the throat; much lassitude, with restlessness and depression of spirits; chilliness or cold chills, especially in the idiopathic; uneasiness and anxiety at the præcordia; twitchings of the muscles of the injured limb, in some cases of the traumatic form; and obstinate constipation in every form of the disease. These symptoms may be of short duration, or they may be experienced for a considerable time: they are followed by pain under or below the sternum, often extending backwards to the spine, by more or less difficulty of swallowing; by pain and stiffness of the neck, &c. To these are generally soon added all the other symptoms which characterise the more partial or limited form of the disease, namely rigidity, pain or contraction of the muscles of the lower jaw.

5. *a. Trismus* may be viewed as the commencement of all the forms of tetanus. With, or following, the pain under the sternum and difficulty of swallowing, the patient complains of uneasiness or stiffness of the muscles of the jaws, neck and throat, and pain in the course of the cervical region of the spine. To these succeed a difficulty in opening the jaws, in masticating or swallowing food, and in rotating or even in moving the head. The muscles which raise the lower jaw assume a state of contraction or tonic spasm, so that the teeth are kept in constant contact (*locked-jaw*). This symptom is first indicated when the patient is desired to show his tongue, and soon is followed by more or less spasm of all the muscles of the face. The angles of the mouth are retracted, the alæ nasi are elevated and the nostrils expanded; the eyes are fixed and prominent, the brows and forehead drawn and wrinkled, the countenance presenting an anxious or distressed expression. In children, or rather in young infants, the disease may not proceed further, as respects the tetanic affection of the muscles, and yet it may terminate fatally, more or less rapidly, either in convulsions or in asphyxia. This limitation, and this course of the malady, are very rare in adults, the state of trismus generally advancing quickly to those about to be mentioned.

6. *b. Pleurosthotonos*, or *tetanus lateralis*, is a predominant spasm of the muscles of one side, drawing the body to that side. This form very seldom occurs. It commences with trismus, or with the affection of the muscles of the face and neck, and often passes into one or other of the forms about to be noticed. The lateral curvature is not always considerable, for it is produced rather by a greater severity of the spasms in one side, than by any limitation of them to that side. I have observed the form in a child, in an idiopathic form, death occurring during a violent convulsion from asphyxia.

7. *c. Emprosthotonos* is the predominant contraction of the muscles of the anterior aspect of the trunk, by which the body is bent forwards, and the head is drawn to the sternum. This state is rarely observed during the whole course of the malady. It may occur for a short time, and be followed by either opisthotonos or tetanus erectus. It, as well as the other forms of the disease, commences with trismus, which in it, as in the others, continues throughout.

8. *d. Opisthotonos* is the bending backwards of the trunk by the excessive action of the muscles of the posterior parts of the neck, back and loins. This is the most frequent form of the disease. The numerous strong extensor muscles of the spine overcome the action of the flexor muscles of the abdomen, and produce a rigid curvature, or posterior concavity, the body resting, during the exacerbations, upon the occiput and heels only; the jaws being also forcibly closed, and the abdominal muscles contracted. This form may be followed by, or may alternate with, the next, the *tetanus proprius.*

9. *e. Tetanus*, although designating any of the forms of the disease attended by general spasm, and being the generic appellation, is often intended to convey the idea of a state of the disease, in which the body is stretched out by the spasms, without being very manifestly bent in any direction — *tetanus erectus*, not *tetanus proprius.* It may follow, in the progress of the malady, either of the states already noticed, presenting at intervals the form of opisthotonos, the posture assumed by the trunk depending upon a momentary or temporary predominance of action of certain muscles or series of muscles; or it may appear in this form consecutively upon the premonitory symptoms, and the partial affection of the face and neck, and preserve it throughout.

10. *A.* ACUTE TETANUS. — This common form of the disease may be either symptomatic or idiopathic. It may result from propagated irritation, and present no satisfactory evidence of inflamma-

tion of the membranes or substance of the spinal medulla; or irritation may superinduce inflammatory action, with the usual symptoms, or even be attended by such symptoms from the commencement, especially in the idiopathic form (See PATHOLOGICAL INFERENCES, &c., §§ 61, *et seq.*) — *a.* After a more or less evident manifestation of premonitory symptoms (§§ 4, 5.), contractions, generally persistent, commence in the muscles of the face and neck — the stage of *trismus*. These contractions extend downwards to the muscles of the back and trunk, and often also to those of the limbs; and the disease assumes either of the forms now stated, but most frequently the two last specified. The jaws generally continue firmly closed; and, although the contraction of the muscles of voluntary motion — of both the trunk and limbs — or the rigidity of these muscles, remains uninterrupted, violent paroxysms or exacerbations of the contraction recur after short intervals, or after from five, to fifteen minutes, and are attended by extreme pain and distress. As the disease advances, the exacerbations become more violent or prolonged; the body is bathed in a warm perspiration; the pain at the præcordium is increased; respiration is laboured, embarrassed, or hurried; and the pulse becomes very rapid and often irregular. The exacerbations are induced by the slightest causes — by a current of air, by attempts to move or to swallow, or by unpleasant sounds, or by a strong glare of light.

11. As the disease continues, the voice becomes altered, harsh, and disagreeable; the larynx is raised upwards, and the tongue is often forced against the teeth during the exacerbations, and lacerated. The shoulders are drawn forward, and the body is either extended or forced into the other positions already noticed, according as the action of one set of muscles predominates over their antagonists. The sense of tightness and the pain under the sternum and ensiform cartilage continue to extend to the spine, and are attended by a laboured, quick, and difficult respiration, and by an agonising feeling of suffocation. The muscles of the face are strongly contracted, whilst the countenance is pale or livid, and bathed in perspiration. The patient expresses the most distressing sufferings, both from pain, and from the difficult respiration, particularly during the exacerbations, which are more frequent, prolonged, and violent as the malady advances, the respiratory muscles, and even the diaphragm, ultimately becoming more or less affected. Owing to this extension of the spasm the patient is carried off by asphyxia, especially in the more acute or rapid traumatic cases; but in the more sub-acute and idiopathic cases, when the disease has been of much longer duration, the severity of the symptoms often abates previously to death, and the patient sinks apparently from exhaustion, but even in these a recurrence, or an extension of spasm, to the respiratory muscles sometimes terminates life.

12. *b.* Such is the usual course of this malady, but each case presents certain modifications of the symptoms during its progress. The earliest or the most constant precursory symptom is obstinate constipation, and this generally continues throughout the disease. The pain at the epigastrium, and anxiety under the sternum, and at the præcordium are the next, and these are very prominent, equally persistent, and generally extend to the spine. Inability to swallow is owing to spasmodic action of the muscles of the tongue and pharynx, and probably also of the œsophagus, often implicating also the glottis, attempts to swallow liquids being often followed by their forcible rejection through the nose and mouth. This state of spasm is such as prevents the introduction of a flexible tube down the œsophagus from one of the nostrils. The difficulty of defæcation, owing to the spasm of the sphincter ani, increases the constipation; and a similar difficulty attends micturition, the urine being sometimes retained, or forcibly ejected by the spasm of the abdominal muscles. The spasms of the muscles of the face occasion remarkable distortion of the features, young persons often presenting the appearance of age. Respiration is chiefly affected during the exacerbations. It is then catching, difficult, and painful; the pain extending from the ensiform cartilage and præcordium to the spine, or darting in the direction of the diaphragm, and being most probably occasioned by spasm of this muscle. The pain in this situation, at an advanced period of the disease, is different from that experienced under the sternum at the commencement. The spasmodic contraction of the muscles is attended by more or less suffering; but this is said not always to be the case. The exceptions are certainly rare; for I have never seen an instance to the contrary, although the distress has been much less in some cases than in others, and experienced only during the paroxysms.

13. The greatest diversity is presented by the extent and severity of the spasms, and by the state of the pulse, in different cases. Whilst in some the muscles of the face and neck, and particularly the muscles closing the jaws, are chiefly or solely attacked (*Trismus*), those of the trunk and limbs being but slightly or not at all contracted; in others, the muscles of the face are much less affected, whilst those of the trunk and limbs are severely attacked. Mr. CURLING, in his excellent work, remarks, that the muscles of the eye are sometimes, but not generally affected. When this occurs, the eye-ball is fixed and drawn slightly inwards, the patient being unable to direct it towards particular objects. Most frequently, however, these muscles are free, the eyelids being half-closed, the contractions of the orbicularis palpebrarum, in this case, being unopposed by spasm of the levator palpebræ. The pupil of the eye has been said to be contracted in tetanus, by some writers, and to be dilated by others. I believe it to be generally contracted; but that it may become dilated with the supervention of the cerebral congestion connected with incipient asphyxia. The muscles of the extremities are less frequently, or less severely, affected than those of the face, neck, and trunk; the forearms and hands being generally the least affected, but much depends upon the seat and nature of the injury, of which the disease is the effect; for the spasms sometimes commence, or are most violent, in the injured limb. When the disease has followed amputation, the spasms of the muscles of the stump and limb are often most distressing. The spasms being thus more or less general and severe, as respects the voluntary muscles, and ultimately extending to the sphincters, and to the

respiratory muscles in the more acute cases, the violent and continued spasms of these latter muscles generally terminating life in these cases, it may be inquired — 1st, whether or no the spasms extend also to involuntary muscles; and, 2d, whether sleep has any influence in relaxing them?

14. 1st. It has been supposed by CURRIE, PARRY, HOWSHIP, TRAVERS and others, that death, in tetanus, is caused by the extension of spasm to the heart. But, with Mr. CURLING, I doubt the existence of spasm of this organ, even as a termination of the disease. There can be no doubt that the inordinate actions of the voluntary muscles occasion a quick return of blood to the right side of the heart at the accession of the paroxysms, and rapidity as well as irregularity of the action of this organ; but any degree of spasm of it would be incompatible with the continuance of life. But, although spasm of the heart is not present in the course of the malady, it may occur and terminate life; and Mr. HOWSHIP has adduced a case, in which he believed, from the state of the heart observed after death, that spasm of this organ was the cause of death. The examination, in this instance, was made eleven hours after death, at which time the body is generally still warm, and the heart firmly contracted. In two most acute traumatic cases, which I examined after death, the heart did not present any appearances different from those observed in cases of sudden or rapid death from other causes. Both these cases terminated in asphyxia. Mr. CURLING refers to a case for which amputation was performed by Mr. LISTON, and in which the vessels contracted so much that there was no hæmorrhage, and ligatures on the mouths of the divided vessels became unnecessary. I am not acquainted with any similar case. The contraction certainly could not have existed to any considerable extent previously to death, otherwise the circulation could not have gone on; the phenomenon being produced by the increased irritability of the coats of the arteries and by their constriction on exposure to the air. It was supposed by Dr. CULLEN and others, that the constipation always observed previously to the accession, and during the course, of the disease is owing to spasm of the muscular coats of the digestive canal; but there is no pain or other symptom referrible to this quarter suggestive of spasm, obstinate constipation generally attending all severe maladies of the nervous centres of animal life, as shown when treating of diseases of the BRAIN and SPINAL CHORD.

15. 2nd. Sleep rarely occurs in acute traumatic tetanus, and only during a few minutes, or in the intervals between the exacerbations, or when the continued contractions in these intervals are not attended by much pain. In the sub acute cases, however, sleep is more frequent, and a more complete relaxation of the muscular contractions takes place; but upon being awakened the full tension of the muscles returns. This circumstance shows the influence of loss of consciousness upon the morbid irritability of these cases, and throws some light upon the pathology of the disease (see §§ 61. *et seq.*). During recovery, and in the less severe cases, and when the intervals between the paroxysms are considerable, sleep may ensue, and the spasms be relaxed, especially as then the effects of the narcotics, so frequently prescribed for the disease, begin to be manifested.

16. *c.* The *pulse* in tetanus has been variously described by different authors. This has been owing chiefly to the different states of the heart's action in the several stages or states of the disease, and the varying grades of frequency in the acute and sub-acute cases, as well as in the idiopathic and symptomatic forms of the malady. Dr. MORRISON, HENNEN, MACGREGOR, and others have remarked, that the pulse is seldom much affected; but the greater number of writers have stated the pulse to be very much accelerated, and most remarkably so in acute cases. This is the result of my own observation in the numerous cases which I have had an opportunity of observing in France and Germany, in 1815 and 1816, and subsequently in warm climates. In an acute case, which I attended in 1820, the pulse was 120 in the minute in the first day of the developed attack. The patient died on the third day. The pulse is generally much less frequent during the intervals than in the paroxysms; but the degree of frequency varies in different cases, as well as in the course of the disease. The treatment adopted has often a considerable influence in quickening the pulse, and towards a fatal issue this is especially the case. The changes taking place in the spinal chord, medulla, &c., and their membranes, according to their nature and amount, also influence the pulse. As the powers of life sink, or are depressed by sedative agents, as by tobacco injections, &c., the pulse becomes remarkably quick, and often feeble. Both the pulse and the respiration are greatly accelerated by the spasms, and hence are varied in character and in quickness with their severity and frequency of accession. During their continuance, especially towards the close of the malady, the pulse is often so frequent, weak, and irregular as not to admit of being accurately counted, whilst the respiration is laboured or gasping.

17. *d.* The *surface* of the body is much warmer than natural, is bathed in perspiration, and is often morbidly sensitive to external agents. The amount of animal heat necessarily varies in different cases — probably from 100° to 106° of Faht. M. PRÉVOST, of Geneva, has stated it to have been much higher (110°), in a case under his care. Dr. BRIGHT says that it was 105° on the third day of the disease. I observed it 105½° in the axilla, on the second day of a case which terminated fatally on the fourth day; and 106° in another which died on the third day. The perspiration is most copious during the exacerbations, and generally has a pungent and peculiar smell. LARREY supposed it to be critical; but Mr. CURLING justly considers this not to be the case. I have seen it the most abundant in the most rapidly fatal cases. A miliary eruption sometimes accompanies excessive perspiration and heat of the skin. The cutaneous sensibility is unusually great, especially to the slighter causes of sensation, as to a light touch, to cold air, &c., and in this the disease resembles the sensitiveness of the surface in RABIES, and in inflammation of the spinal membranes (see SPINAL CHORD, § 135.).

18. *e.* The *urine* is generally in small quantity in tetanus, as may be supposed from the excessive perspiration, and it is usually high-coloured. It is more abundant in the sub-acute form of the

malady. The bowels are always constipated, and are moved with great difficulty; the stools, however, present no very remarkable disorder, beyond what is usual from retention. The tongue is commonly white and moist at the commencement; but it is often dry, with the papillæ erect as the disease advances, and thirst becomes urgent. When tetanus or trismus is fully developed, the tongue can seldom be satisfactorily shown.

19. *f.* The *senses* are acute during the course of the disease, especially sight, hearing, and touch, and are remarkably susceptible of their respective stimuli. The functions of the *mind* are unimpaired, even during the most distressing exacerbations, and any degree of delirium is rarely observed until shortly before dissolution, and then it may sometimes have been occasioned by the narcotics which had been prescribed.

20. *g.* The state of the *blood* has not been satisfactorily observed, either in the idiopathic or symptomatic form of the disease. I have seen it without any particular change in one case, and both cupped and buffed in another; and slightly cupped only, in two; but one of these cases was only once accidentally seen by me. The question is, whether or no this state of the blood is connected with, or a manifestation of, inflammatory action in the animal nervous centres, or merely the consequence of the inordinate muscular action; but this involves the consideration of the pathology of the disease. Admitting that there is inflammatory action of these centres, or at least of their envelopes, in some cases, as there undoubtedly is in the idiopathic states of the malady, there must necessarily be some degree of fever; and this state of the frame is said not to exist in traumatic tetanus. Mr. Curling observes that this form of the malady "is generally unattended by fever; and Dr. Cullen, Dr. Clephane, and Dr. Chalmers, and many other authors have remarked that the blood very rarely possesses an inflammatory character." Mr. O'Beirne states that he witnessed about two hundred cases of tetanus; but he never saw one accompanied with fever. It may certainly be admitted, that, in the traumatic form of the disease, fever is not often observed at its commencement, and that the febrile symptoms enumerated above, especially the quick pulse and respiration, the hot skin, the copious perspiration, thirst, and excited papillæ of the tongue, are chiefly the consequences of the violence of the muscular contractions; yet, in many cases, these symptoms (if not febrile, what are they?) are partly to be imputed to increased vascular action — an action excited by the irritation propagated to the spinal chord and medulla oblongata, and thence reflected upon the voluntary muscles, the inordinate action of these muslces developing increased vascular determination to the origins of the spinal nerves, and to the spinal chord; this determination, advancing to morbid action, perpetuating the muscular contractions, extending their spheres, and ultimately terminating in very many instances, by implicating the respiratory muscles, even the muscles of the glottis as well as those of the pharynx.

21. *B.* Sub-acute and other States of Tetanus. — When an attack of either idiopathic or symptomatic tetanus is less severe than that described above, especially during the second and third days, or when its severity is partially subdued, it may continue in a sub-acute or milder form for several days, or even for three, four, or five weeks. This state of the disease has been usually termed *chronic;* but it hardly can be called so, as respects either the character or duration of the disease. In this less acute or milder form the symptoms are nearly the same as in the acute, especially at an early period, but they either are, or become, less severe. The intervals between the paroxysms are longer, and the paroxysms are shorter, or the spasms are milder. The pulse also is either less frequent or but little accelerated during the intervals, and the contractions are less general or continued than in the acute form. The symptoms thus gradually subside, and the natural functions assume their healthy states. But the muscles continue for some time stiff or sore; and they are liable to a return of stiffness or contraction after exposures to either cold, wet, or miasmatous exhalations.

22. *The sub-acute or mild form* of tetanus may present an intermittent character, especially when it is idiopathic, owing to the concurring influence of malaria with wet and cold in causing the attack; but this modification of the disease is only met with in warm climates and in miasmatous localities. In females, trismus, or sub-acute tetanus, may assume an *hysterical character*, or hysterical symptoms may be associated with the tetanic, the disease being really tetanus, and occasioned by an injury. Of this association I had a very remarkable instance, many years ago, in a cook in my own family. This state of the disease should be distinguished from hysteria, when the latter assumes a tetanic form, owing to the violence of the spasms during the hysteric paroxysm (See Diagnosis, § 35.).

23. But tetanic symptoms may be produced in females by the usual causes of tetanus, especially during the catamenia, or after an abortion, or after parturition, especially if any portion of the ovum, or membranes, or placenta be retained. In these there is sometimes much of the hysterical character, but the tetanic may so predominate as to place the patient's life in jeopardy. Of this I saw a case to which I was called in consultation some years ago. I was convinced of the retention of a portion of the ovum. A decoction of secale cornutum with the biborate of soda was prescribed, terebinthinate enemata were administered, and terebinthinate embrocations applied along the spine. The cause of irritation was discharged from the uterus, and the patient recovered.

24. *C.* Terminations.—A *fatal issue* is most commonly occasioned as now stated. In this case, the paroxysms become more severe and prolonged, and the pulse most frequent, feeble, and irregular. Respiration is difficult, hurried, laborious, and unequal. The motions of the chest and of the diaphragm are impeded; and the lips, face, and surface become first pallid and then livid. The lungs are congested, and air ceases to be either inhaled or expelled. It has been supposed that, during the paroxysm, asphyxia may be occasioned by spasmodic closure of the glottis, the spasms extending to this quarter chiefly or only; and that death is thus suddenly produced during the exacerbation; and it has also been inferred that spasmodic closure of the glottis is superadded to

spasm of the muscles of the chest and diaphragm. Whether either mode takes place solely, or both co-operate, in occasioning the fatal result, is a matter not easily determined; but it is of some importance that it should be ascertained, as indicating an extreme measure of treatment in imminent circumstances. Whilst death is thus generally occasioned in the acute cases, it is imputed chiefly to exhaustion, in the sub-acute, or chronic as commonly termed; the prolonged disease, the inability to receive nutriment, the return of spasms, and the consequent exhaustion and inanition terminating life. But, even in these, spasm may affect the muscles of respiration, or even the glottis, and produce death. When exhaustion or inanition occasions this termination, the paroxysms become weaker and less frequent; the pulse small, weak, irregular or intermittent; the muscles relax; the features sink; the eyes are dim, or are covered by a slight film; and respiration is gasping, slow or laboured, or it gradually and almost insensibly ceases.

25. Recovery from tetanus is commonly gradual. In a table where Mr. Curling has arranged 128 cases of traumatic tetanus, fifty-eight terminated successfully: eight being cured in the course of a week; three in ten days; four in a fortnight; four at the end of three weeks; fifteen at the end of a month; four after five weeks; eight after six weeks; three at the end of eight weeks; three after two months; and in two after three months. The muscles often continue stiff for some weeks after the spasms have subsided, owing to the injury received by them during the attack. Even months may elapse before they regain their healthy tone and action. In a case recorded by Dr. Currie, the patient's features retained "the indelible impression of the disease." And, in a case by Mr. Curling, the patient complained of stiffness about the jaws when exposed to cold, although nine months had elapsed from the attack; and, in another case, rigidity of the muscles of the lower jaws continued for six months after recovery. A few days before this was written I was consulted by a gentleman, whose jaws had continued so firmly locked, after an attack of idopathic trismus, that some of the front teeth had been extracted to enable him to receive food into his mouth. This contraction of the muscles of the jaws had continued nine years, without any change. He had become accustomed to it, and he now consulted me for a different ailment. The treatment of these effects of tetanus is a matter of importance, as will appear in the sequel.

26. *The duration of tetanus* varies very remarkably, both in the idiopathic and symptomatic forms. This is well shown, as respects the latter form, by the table compiled by Mr. Curling. Professor Robison has stated that a negro having scratched his thumb with a broken piece of china, was seized with tetanus, and died in a quarter of an hour. In one case, the patient died in twelve hours; in another, recorded by Mr. Dickinson, death took place in twenty-two hours; and, in a case contained in Mr. Curling's table, in twenty hours. In another, fully detailed by this excellent writer death occurred sixteen hours after the first appearance of tetanic symptoms, and six days after the injury. This termination is frequent at various periods from twenty-four to forty-eight hours. In the table just mentioned, fifty-three cases were fatal within eight days after the appearance of symptoms: eleven on the following day; fifteen on the second day; eight on the third; seven on the fourth; three on the fifth; four on the sixth; three on the seventh; and two on the eighth day after the commencement of the disease, but very few after a longer period. Morgagni mentions a case which was fatal after twenty days. Dr. Lionel Chalmers, in his account of acute idiopathic tetanus in South Carolina, assigns the duration of this form of the disease nearly to that of the traumatic form now quoted from Mr. Curling. Dr. L. Chalmers states that patients generally die in twenty-four, thirty-six, or forty-eight hours, and very rarely survive the third day; but, when the disease is less acute, that few are lost after the ninth or eleventh day.

27. *D.* Appearances in Fatal Cases.—Different changes have been observed in different cases, and those which have been found in some have been absent in others. Certain changes are, however, more constant, and are rarely altogether absent.—*a.* The *body* generally is unusually rigid after death; and the *muscles* are not only firm or contracted, but they also present, in many places, rupture of their fibres and ecchymoses.* The *blood* is always uncoagulated, and hence it gravitates to the more depending parts, and gives those parts externally a livid or dark mottled hue. The combination of rigidity of the muscles with fluidity of the blood shows that the *rigor mortis* is not the result of the coagulation of the blood in the structures; this state of the muscles being evidently owing to the morbidly increased irritability before dissolution, the remains of which still continue in their fibres for some time after death.

28. *b.* The *nerves* immediately connected with the seat of injury, are stated by some writers to have been injured, inflamed, or otherwise changed; and by others to have been in no ways affected. Even when presenting manifest appearances of inflammation, they have been viewed as merely participating in a similar state of the surrounding parts. In some cases, however, the inflammatory changes have not been confined to the portions of the nerves in the seat of injury; but have been traced in different parts of their course as far as their origins. Many recent observers have traced these changes along the nerves to the pia mater, the arachnoid, and the substance of the spinal chord, which have usually also presented evidence of inflammatory action. Some instances have occurred to these and other observers (see Bibliog. and Refer.), in which injury of the nerve has existed, or causes of irritation have been in contact with the nerve, without signs of inflammatory action. As respects the nerves, therefore, the

---

* Mr. Bowman (*Philos. Transact.*, 1841, p. 69.) has found some muscles in tetanus apparently healthy, whilst others presented a pale appearance in many parts, like the muscles of fish, arising probably to the blood having been squeezed out of the vessels. In other parts they had almost lost their fine filamentous structure, and presented a soft spotted mass which was easily torn. Extensive ecchymoses were frequent, and contrasted with the pallor of other parts. Under the microscope, the primitive fasciculi exhibited, here and there, the characteristic signs of extreme contraction, fusiform swelling, and a closer approximation of the transverse striæ than usual. In other parts, these fasciculi were reduced in size, and the striæ were either far apart, or had disappeared entirely. In many parts they had burst with the sheath.

proofs of change, although evident in many instances, are wanting in others; but it is by no means certain that, although changes perceptible to the unaided senses have been wanting, no change has existed, or that irritation of a most violent kind may not have been propagated along the nerves without developing inflammation, or changes usually termed inflammatory, sufficiently great or manifest to remain many hours after death.

29. *c. The ganglia and sympathetic nerves* were suggested by me, in a paper published in the *London Medical Repository* for May, 1822, to be the seat or pathological cause of tetanus, and especially of the idiopathic form of the malady. I then contended, that the ganglial, or the organic nervous system, is the source of irritability in contractile tissues; and when this property is inordinately excited, without the control of the will, that changes should be looked for in this system. Some years subsequently, Mr. Swan directed attention to the sympathetic system in tetanus, and stated that the ganglia were preternaturally injected in this disease; and appearances said to support this statement were observed by Andral, Aronssohn, and Dupuy; whilst Meyer, Vetter, and others, have adduced instances of tetanus consequent upon ossific deposits irritating branches of ganglial nerves. It should not, however, be overlooked, that the ganglia are often very vascular, even in health; that they are not always, or even generally, unusually or excessively vascular, and much less manifestly inflamed, in tetanus; and, even granting them to be excessively injected or inflamed, it cannot be shown that their inflammation could be more productive of tetanus, than a state of irritation or of vascular erythism, this latter condition being manifestly more compatible with excessive discharge of function, than a state of inflammation.

30. *d. The Spinal Chord, Medulla Oblongata, Brain, and their Membranes,* have frequently presented changes more or less decidedly morbid, in tetanus and trismus. I believe that these changes are rarely altogether absent, especially as respects the spinal chord, medulla oblongata, the pons Varolii, and their membranes, when the inspection is made within twenty-four hours after death, and when these parts are carefully examined. Something, however, should be imputed, as respects both the presence and the absence of change, to the fluidity of the blood after death, and to the position of the body. In no inspection which I have witnessed, have inflammatory appearances in one or other of these parts been altogether wanting. These appearances have been viewed as the pathological cause of tetanus by the Franks, Larrey, Magendie, Brera, Recamier, Reid, Kennedy, Ollivier, Castley, and many others, whose writings are referred to in the Bibliography; and when tetanus or trismus has been present, and these changes have been slight or absent, the circumstance may be explained without inferring that these parts were either unaffected or unchanged, even in their vascular conditions during life (see §§ 63, *et seq.*). The changes more commonly observed are, vascular injection of the pia mater, sometimes with exudations of lymph on its free surface; hardening or softening of one or more of the columns of the chord or of the medulla oblongata, softening being more frequently observed when the inspection has been long delayed; opacity of the arachnoid, or deposits of small plates of bone or of cartilage in the free arachnoid, the surface of these plates being rough on the sides next to the pia mater; generally increased vascularity, sometimes with recent adhesions, and congestion of the veins and veinous sinuses of the spine. These changes may extend more or less generally along the chord and medulla oblongata, often also to the pons Varolii, and even to parts in the vicinity of the latter, and surrounding the fourth ventricle. They were thus observed, with several ossific plates in the arachnoid, in an acute case of tetanus which was under my care in 1820, and of these appearances I made a coloured drawing, which is still in my possession.

31. In addition to these, the substance of the chord and medulla is somewhat reddened or injected, and exhibits numerous red points when divided. In some cases, the membranes are more decidedly inflamed and thickened. Generally, the spinal fluid is abundant and somewhat altered or turbid. In rarer instances, a puriform exudation is found between the membranes, and the softening of a portion of the chord presents a puriform infiltration with capillary injection. In still rarer cases, the serous exudation is of a rose colour, or even more deeply tinged, or even blood is extravasated and extended along a considerable part of the chord. These are the chief changes which are observed in the spinal medulla in fatal cases of tetanus; but nearly all the appearances described when treating of *inflammation of the membranes and substance of the* spinal chord and medulla oblongata, are sometimes found in cases of tetanus and trismus, especially in the idiopathic form; whilst in some cases, more particularly of the traumatic form, no changes in the spinal chord, medulla oblongata, or their membranes, or in the ganglial nerves, or even in any other part, have been detected; but, whether the examination in these instances has been sufficiently minute or not, may be viewed, in the present state of our knowledge, as somewhat doubtful.

32. The morbid appearances which have been constant in the cases which I have inspected, chiefly, however, many years ago, were, injection of the membranes and substance of the more central parts of the base of the brain — the medulla oblongata, the pons Varolii, and parietes of the fourth ventricle. Numerous cases illustrative of the pathology of tetanus have been detailed by Mr. Curling; and to his work, as well as to others, and to many interesting papers referred to in the Bibliography, I refer the reader.

33. The changes which have been found in these parts of the animal nervous system admit of more than one interpretation, and manifestly supervene in two ways:— 1st. They may be induced primarily, especially in idiopathic tetanus, the seat and extent of the inflammatory action along the medulla oblongata and chord, occasioning the extended and the continued contractions, and the spasmodic exacerbations. — 2nd. They may be merely consequences of the irritation conveyed to the spinal medulla and membranes, or to the medulla oblongata, or parts in its vicinity, by nerves proceeding from the periphery of the frame, or by communicating nerves from internal ganglia

or viscera: the irritation, thus extended and reflected by motory nerves on the voluntary muscles, excites increased vascular action; and this increased action in many instances advances to inflammation, or to the production of changes, either resembling, or identical with those said to be inflammatory. (See *Pathological Inferences*, &c. §§ 61, *et seq.*).

34. *e.* In addition to the above, changes have been found in other parts of the body. The *lungs* are usually congested, and the blood in the vessels is dark and fluid, owing to the immediate cause of death — the state of asphyxia. Increased vascularity or inflammatory injection of the digestive *mucous surface* has also been seen by M'ARTHUR, SWAN, ANDRAL, and others; but this change may also have resulted from the asphyxia, or from the medicines prescribed. Injection of the *ganglia* has been remarked by SWAN, myself, and others; but this, if it at all exceed the natural state, may be only the result of propagated or transmitted irritation. The existence of *worms* in the intestines and stomach in a very large proportion of cases, of both the idiopathic and symptomatic malady, especially the former, is interesting, at least as a predisposing cause; and instances of this fact have been recorded by MURSINNA, O'BIERNE, LARREY, LAURENT, DAZILLE, THOMPSON, MORGAGNI, STOLL, and many others; and great importance has been attached to them as a cause of tetanus by these writers. "The papillæ maximæ at the root of the tongue are sometimes found hypertrophied, and the mucous lining of the *larynx* highly injected, and containing a quantity of frothy mucus." (CURLING.) — The *pharynx* and upper portion of the œsophagus are much contracted, and their internal surface is red and inflamed, and often covered with a viscid reddish mucus. Similar appearances are also found in cases of RABIES (see § 22.). In both maladies the spasms of the pharynx explain the changes of these parts.

35. II. DIAGNOSIS. — Tetanus can hardly be mistaken for any other malady.—*a.* The continued contraction of the muscles of the jaws and face; the peculiar pain under the sternum; and the exacerbations of the continued muscular contractions, viewed in connection with the cause, when this is known, sufficiently indicate the malady. — *b.* It may, however, when superficially viewed, be mistaken for *rabies* (or hydrophobia, as that malady has improperly been termed), owing to the difficulty of swallowing fluids, to the accession of spasms of the muscles of the face and neck upon attempts to swallow, and to the increased sensibility. But the entire absence of muscular contraction during the intervals between the paroxysms, and the morbid impulse and ferocity characterising the rabid paroxysms, distinctly mark that disease, and distinguish it most satisfactorily from tetanus.

36. *c.* Tetanus can hardly be distinguished from *inflammation of the membranes of the spinal chord and medulla oblongata*, especially idiopathic tetanus. Indeed this latter, and even the symptomatic, may be viewed as often being very acute forms of inflammation attacking almost simultaneously the arachnoid and pia mater of the chord and medulla oblongata, and occurring either primarily or consecutively of irritation propagated to these parts (§ 33.); the extent of the morbid action occasioning a co-ordinate extent of muscular contraction. When treating of meningitis of the chord, and of myelitis (see SPINAL CHORD, §§ 127—157.), I described the symptoms, as respects the voluntary muscles, as being identical with tetanus or trismus, according to the seat and extent of disease of the spinal membranes. Inflammation attacking either these membranes, or the chord, or the medulla oblongata, or extending to them all, will necessarily be followed by effects, as respects the muscles especially, varying with the changes produced in these structures by the inflammatory irritation or action, of which they are either successively or co-etaneously the seats. For, if the morbid vascular action in these tissues be not followed by either effusion of lymph, or softening of the chord so as to occasion abolition of function (paralysis), it must necessarily follow, that the increased muscular action, produced by the vascular action in the membranes of the chord, will be continued either until the vascular action subsides or is subdued by treatment, or until it extends to the membranes or substance of the medulla oblongata and central parts of the base of the brain, and occasions spasm of the respiratory muscles and asphyxia. In many cases the inflammatory action in the membranes or substance of the spinal chord is limited to a portion only of either, or of both, and the consequent changes are such as occasion paralysis, the tetanic contractions described, in the article referred to, being partial and co-ordinate with the extent of disease in the chord, and either preceding the paralysis, or co-existing with paralysis, but in a different series of muscles. Instead, therefore, of viewing tetanus and trismus, especially in their idiopathic forms, as totally different diseases from inflammation of the membranes of the spinal chord and medulla oblongata, I consider them very closely allied, although not identical maladies, the chief differences arising from the extent to which these membranes are affected, from the development of muscular irritability being greater in the one disease than in the other, and from the changes consequent upon the irritation or inflammatory action of which they are the seats.

37. *d.* It ought not to be overlooked that *Hysteria*, especially in its more paroxysmal and spasmodic form, may very closely simulate one or other of the forms of tetanus. Of this I have observed several very remarkable cases; the closeness of resemblance being such as would have induced a physician, who had seen the case for the first time, to believe that the patient was actually the subject of tetanus. Generally, however, these hysterical tetanic seizures are preceded and attended by so many hysterical phenomena that the difficulty of diagnosis is slight. But this is not always the case; for the trismus, or the more general tetanic contractions, may be so protracted, and the symptoms of either opisthotonos, or emprosthotonos, be so complete, as to lead to the conclusion, which the observation of some cases has confirmed, that the irritation of the sexual nerves has so excited the spinal chord or membranes, or the origins of the spinal nerves, as to develope a tetanic state, owing to the reflection of this irritation, from the chord and origins of the voluntary nerves, upon the muscles of voluntary motion. The nature of these hystero-tetanic seizures, even when prolonged, may be inferred from the sex and age of

the patient, from the history of the case, from co-existing hysterical symptoms, and from the rapid effect produced by influences acting strongly on the mind, or powerfully exciting volition, as preparations to apply the actual cautery, or the cold affusion. It may further be mentioned, that cases may occur (I have seen three undoubted instances) of simulated trismus or tetanus in hysterical females, especially in those who addicted themselves to self-pollution. The test just mentioned will often aid in the detection of these cases, and often present the recurrence of the hysterical form of trismus or tetanus. The trismus, or more fully developed tetanus, occurring in rare instances after parturition or abortion, is often attended by hysterical symptoms, and hence requires close attention to distinguish it from some states of hysteria; the alliance in such cases being close. Although *epilepsy* is attended both by trismus and tetanic spasms, yet the characteristic unconsciousness of the former sufficiently distinguish it from the latter.

38. III. TETANUS INFANTUM.—SYNON. *Tetanus vel Trismus Nascentium ; Tet. vel Tris. Neonatorum ; Tet. or Tris. of new-born Infants.* — *The Tetanus* or *Trismus* of recently born infants is essentially the same disease as that already described. It generally commences in the first seven or nine days after birth, and rarely later than the fourteenth day. The muscles of the lower jaw are first affected, hence it has been frequently named trismus ; but the spasms are rarely limited to these, but commonly extend to the other muscles of the face, and to those of the neck, trunk, and also of the limbs. Even when the spasms are apparently confined to the muscles of the jaws, a paroxysm of more general spasm suddenly occurs and terminates life by asphyxia. The tetanus of infants usually presents two forms, as in the tetanus of adults, but is even more rapid in its progress than the latter — the *acute*, which commonly terminates life in ten or thirty hours, or within forty-eight hours ; the *sub-acute*, which may be prolonged to eight or nine days, but more frequently terminates from the third to the fourth or fifth. Recovery from either of its forms is very rare.

39. This malady is now very rarely observed in temperate climates, and formerly not frequently, unless in Lying-in-Hospitals, in which it has appeared as a most fatal endemic. According to Dr. JOSEPH CLARKE, it proved fatal to many of the infants born in the Dublin Lying-in-Hospital. At the conclusion of 1782, of 17,650 born alive in that institution, 2944, or about 17 per cent., had died of it within the first fortnight from birth. But it is chiefly among the dark races, and the negro slaves especially, that it is most frequently met with. Mr. MAXWELL, Dr. HANCOCK, Dr. MORRISON, and others state that it is a chief cause of depopulation in the negro races in the West India Isles, and in the colonies of Demerara and Essequibo, the deaths of new-born infants from this malady being about cent. per cent. of all that are born. According also to RUSH, FOURCROY, VALENTIN, DAZILLE, CAMPET, and others, it is also a frequent, and always a fatal disease in the southern or slave states of the United States, but that it is rarely seen in white infants. According to Dr. HOLLAND and Sir GEO. MACKENZIE, it is destructive to all the infants born in the island of Haimacy, on the south coast of Iceland, and it exists in St. Kilda, the most remote of the western islands of Scotland ; this prevalence being imputed chiefly to the food given to infants.

40. *The causes* of this disease of infants have been very differently assigned by writers. By some it has been imputed to the division of the umbilical chord, and by the subsequent treatment, and hence it has been viewed as traumatic tetanus in the infant ; by others it has been considered as idiopathic, and caused chiefly by a vitiated atmosphere, from crowding and deficient ventilation ; and by many it is said to be owing to the retained meconium, and to morbid secretions in the prima via ; whilst not a few impute its frequent occurrence in the West Indies to the excessive use of irritating purgatives soon after birth. All these causes have been disputed, and exposure to cold, or currents of air, has been assigned as its chief agent. That more causes than one are concerned in producing it seems most probable, and, in connection with the division of the umbilical chord, an impure air, currents of cold air, unwholesome and inappropriate nutriment, and irritation of the digestive canal either by morbid secretions and excretions, or by unsuitable purgatives, may concur in developing the malady, in those constitutionally predisposed to it, as negro infants appear to be, especially in some localities. That a contaminated atmosphere is concerned in causing the malady in white infants is shown by the fact, that the very remarkable fatality occasioned by it in the Dublin Lying-in Hospital, and noticed above (§ 39.), was reduced, after the date there stated, from seventeen per cent. to five per cent. by a better ventilation of the institution.

41. *The appearances in fatal cases* have been very differently described. But, although nearly every case has been fatal, and numerous opportunities of inspection have been furnished, still the changes produced by the malady have been very imperfectly observed. Until early in the present century the spinal chord and parts in the vicinity of the fourth ventricle were rarely or never examined, even in this and other forms of tetanus ; and as various concomitant or contingent changes were remarked by writers in different tissues and organs, so these changes severally received the credit of directly or pathologically producing the disease. Various changes of an inflammatory kind have been observed in parts in the vicinity of the umbilicus; whilst several of these changes have been considered such as necessarily follow the division of the chord. Dr. GOELIS of Vienna was among the first to examine with attention, although preceded by the FRANKS, the spinal chord and medulla oblongata, in the cases which occurred in the foundling hospital of that city; and he, as well as others subsequently, has always observed increased vascularity of the membranes and substance of those parts of the animal nervous centres. Indeed, according to my own observations in a few instances, and to those of other writers who have always inspected these parts, not only in cases of trismus and tetanus, but also in fatal cases of epilepsy and convulsions, morbid appearances, either congestive or inflammatory, and often also their usual consequences, have been observed in these situations, and in the more central parts of the base of the brain, and hence

we have no reason to infer that the pathology of the tetanus of new-born infants is in any material respect different from that of the tetanus of adults, the only difference being in the greater severity, acuteness, and fatality of the former; and as far as my own observation has extended, in the more marked inflammatory appearances, or the extremely increased capillary injection of the nervous centres of both organic and animal life.

42. IV. Relations and Alliances of Tetanus and Trismus to other Diseases.—i. Certain of these *Relations* have been already noticed when noticing the *Diagnosis* of Tetanus and Trismus, but there are others which should not be overlooked, especially as they serve to throw light on the nature and treatment of this malady. When treating of inflammation of the membranes of the Brain and of the Spinal Chord, I stated that spasm, more or less constant or persistent, is present in the muscles supplied with nerves, the origins of which are more immediately connected with the inflamed part, and that the spasm continues until pressure or disorganization, at the origins of these nerves, destroys their functions. When irritation is propagated from remote or distant parts to the membranes of the cerebro-spinal system, the effect produced may be longer persistent, than when inflammation is primarily developed in these membranes; for, in the former case, the irritation may continue long before inflammation is developed, whilst, in the latter, the primary existence of inflammation may be more rapidly followed by exudation, thickening, and other inflammatory changes calculated to impair or destroy the functions of their seats and of adjoining parts. Hence in most cases of spasm, convulsive disease, and tetanus, the nature and rapidity of the fatal result depend either upon the extension of the irritation to parts intimately connected with the origins of nerves supplying vital parts, or to the inflammation and consequent changes at or near the origins of these nerves.

43. *A.* In *cerebral* or *spinal Meningitis* there is generally spasm of muscles supplied by nerves, the origins of which are allied to the irritated or inflamed portion of membrane; and, when the membranes of the basilar parts of the brain are affected, the spasms are the more general and severe or fatal. In the convulsive or spasmodic affections of infants or children, the great difficulty often is to determine whether the attack proceeds from disease existing primarily in the brain or its membranes, or from irritation and consecutive morbid action propagated thither from distant or remote parts; and even when the latter is most evidently the case, it is not the less difficult to decide how far the propagated irritation may have affected the membranes or substance of those parts of the cerebro-spinal centre to which it had extended. The spasmodic attacks of infants and children, whether tetanic or convulsive—whether persistent or momentary —generally depend upon certain pathological conditions, which are usually simple, or unassociated at their commencement, but which are not infrequently complicated in their advanced progress. These conditions may be — 1st. Irritation or vascular erythism in, or implicating, the more central parts of the base of the brain, or of the membranes.—2d. A similar state affecting some portion of the spinal medulla.—3d. Inflammatory action, at an early period of its progress, or before the consequent organic changes have abolished the functions of the nerves proceeding from the seat of morbid action in either the brain, or spinal chord, or their membranes. — 4th. Irritation primarily affecting some portion of the digestive canal, and propagated thence to either the chord, or brain, or their membranes.—5th. Irritation existing in the gums, or in other parts more or less remote and similarly propagated. — 6th. Morbid states of the blood, arising either from the absorption of morbid matters, or of poisonous articles, or from self-contamination, consequent upon the failure or arrest of some depurating function, and affecting the substance or membranes of the cerebro-spinal centre.

44. It will follow, from a due consideration of the usual procession of morbid action, that the disorder, whether denominated irritation, erythism, morbidly exalted nervous function, &c., commencing originally in either the *fourth* or *fifth seats* — in either the digestive canal or other parts—will frequently, and after various periods, superinduce either the *first*, *second*, or *third* of these pathological conditions, or all of them in succession; and whilst they, severally or singly, are attended by spasm, more or less persistent or momentary — tetanic or convulsive, continued or paroxysmal — the great difficulty which the physician will have to contend with, is to decide respecting the origin and seat of disorder and the progress it has made, conformably with the procession of morbid actions now demonstrated. To ascertain these points with due precison, also, the remote causes, the more immediate effects of these causes, and the whole history and progress of each case require accurate examination; and the functions of parts deriving nerves from the several sources already indicated should be duly investigated. The accession, the progress, and termination of each attack — paroxysmal or more or less persistent—ought to be carefully and closely observed, in respect—1st. Of the functions of ingestion, digestion, and defæcation.—2nd. Of respiration, circulation, and vascular action. — 3rd. Of the functions of sense, and of altered sensibility. — 4th. Of cerebral manifestations and consciousness.

45. When there is, in connection with spasmodic or tetanic action, increased sensibility of the surface of the body, the membranes of the spinal medulla are obviously implicated. If with these symptoms there be also a morbid exaltation of the senses of hearing, seeing, &c., the extension of irritation or of inflammatory action to the basilar parts of the brain may be suspected. If the spasm be accompanied with anæsthesia of the surface, either consecutively upon increased sensibility, or primarily, or with impairment or loss of the functions of sense, the presence or supervention of congestion, or of effusion, or of softening, in those parts of the nervous centres, upon states of irritation, erythism, or inflammatory action, may be inferred; the extent and seat of spasm, and of impaired or lost sensation, indicating the seat and extent of the pathological condition. If in connection with, or consecutively upon, spasmodic contractions, there be loss of all consciousness — of all the functions of sense, and all the manifestations of mind — as in epilepsy, and in puerperal and some other forms of convul-

sion, &c., it may be inferred, that the irritation, whether cerebral, spinal, or in parts remote from these centres, so affects the medulla oblongata or the central parts of the base of the brain as to occasion spasm of the respiratory muscles, especially of the glottis and diaphragm, or to paralyse or arrest their functions, either for a time or fatally; if for a time only, the cerebral congestion attending the paroxysm and the imperfectly oxydised blood serve to dissolve the spasm by paralysing for a brief period the previously irritated nerves, a return of the normal state of the functions ultimately resulting; if fatally, the protracted spasm and the consequent congestion and asphyxia terminate existence.

46. The views now stated explain the alliance of tetanus or trismus with the spasms or convulsions of infants and children, as well as of adults; for, as long as the parts of the base of the brain, which are more intimately connected with conscious sensibility, are not implicated in such a manner as to abolish their functions either for a time or for ever, the attack is simply spasmodic or convulsive, consciousness and mental manifestation being unimpaired. When, however, the powers of mind and consciousness are affected, the extension of disease to the brain, or the primary affection of some part of this organ, is made manifest, and the attack is either epileptic or apoplectic, according to its mode of accession or to the phenomena attending and following it.

47. *B.* In *Epilepsy* and in the *epileptic convulsions of the puerperal states*, there are present not only the spasms of the muscles of the neck and face, but also most of the other phenomena of tetanus, in either of the forms already defined, often modified, but sometimes almost identical with them, although generally of a short or paroxysmal duration. The chief distinction, however, is in the sudden accession of unconsciousness which is generally contemporaneous with, or somewhat antecedent to, the spasm. In all cases of spasm or convulsion, accompanied with unconsciousness, the muscles of respiration are early affected, and cerebral congestion and imperfect oxygenation of the blood result, these conditions tending to dissolve the spasms, and thereby to admit of the return of a normal state of respiration, if they are not so excessive or persistent as to destroy life.

48. *C.* In *Apoplexy*, and more especially in that form which was first described by me under the name of *convulsive apoplexy*, tetanic rigidity of muscles, more particularly of those of the neck or limbs, with various convulsive movements, is more or less manifest. Although in these cases the vessels of the brain are very frequently diseased, and the substance of the brain consecutively altered, with hæmorrhagic clots, yet the spasms, tetanic contractions, and convulsive movements are not to be imputed so much to these and other allied alterations in the substance of the brain, as to changes in the membranes, especially in those parts which cover the central and basilar parts of the cerebrum.

49. *D.* The tetanic spasms and convulsions observed in the more violent *paroxysms of Hysteria* are seldom accompanied with unconsciousness; or, if they be so attended, the loss of sensation is incomplete, and supervenes gradually, whereas it is instantaneous and complete in the fully developed fit of epilepsy; and it comes on gradually or suddenly, or is incomplete or complete in convulsive apoplexy, the contractions of the muscles being either very extended or limited in either malady. The chief differences in the spasmodic or muscular contractions, characterising these diseases and the several forms of trismus and tetanus, are that they are either subordinate phenomena, or of comparatively short duration in the former, whilst they constitute the characteristic feature, the most dangerous symptom, and the cause of death, in the latter.

50. *E.* In the tetanic contractions characterising the *convulsions of infants and children*, especially the form termed *eclampsia*, there is generally more or less affection, primary or propagated, of the cerebro-spinal centres, or of their membranes. If the brain be unaffected, the functions of sense and consciousness are not materially disturbed during the attack; but if these functions be manifestly impaired or lost, the mischief is in the brain or its membranes, or is propagated thither either along the spinal chord or its membranes, or directly from the seat of irritation, by means of the ganglial or sympathetic nerves. In young children and infants, when the irritation is in the stomach, or in the bowels, or in the gums, it is often difficult to determine whether the muscular contractions are attended by loss of consciousness or insensibility. In many cases they are not thus associated, as evinced by the senses of sight and hearing, by the sensibility of the surface, and by the free and unembarrassed cry; this last more especially indicating, that the function of respiration is unaffected. In other cases, even when the irritation is seated in one or other of these parts, the cerebro-spinal centres may not be implicated at first, but they may become affected sooner or later, and be the chief seat of disease, as commonly observed in other convulsive maladies attacking either children or adults. (See arts. CONVULSIONS, §§ 22, *et seq.*, and SPASM.)

51. ii. THE EFFECTS OF MUSCULAR CONTRACTIONS ON THE CIRCULATION have not received sufficient attention from pathologists. It is manifest that the changes produced on the circulation by muscular contraction, inordinate either in degree or in continuance, will vary with these conditions, and with the muscles affected. The provisions so wisely made as to the return of blood from the brain and spinal chord: the sinuses within the cranium, and the venous sinuses of the spinal column are so arranged, as very greatly to diminish or to counteract the ill effects of arrest of the return of blood from these organs; nevertheless more or less obstruction to the return of blood from them is produced by violent or protracted spasm, chiefly by pressing upon venous trunks, or by interrupting the passage of air into the lungs, or by preventing the relaxation, or by continuing the contractions, of those muscles, upon the alternate relaxation and contractions of which respiration depends. In these cases, the right auricle of the heart becomes over distended, the return of blood from the brain impeded, the liver becomes congested, and the circulation through the lungs insufficient for the oxygenation of the blood; asphyxia and cerebral congestion being the ultimate results.

52. iii. THE INFLUENCE OF THE BLOOD ON MUSCULAR CONTRACTION is even greater than that of muscular action on the circulation. Ac-

cording to the states of the blood circulating through muscular parts, the contractions of these structures may be exalted, spasmodically excited, or weakened, or even altogether abolished. Much of these states is doubtless owing to the influence of the blood upon the nervous centres, from which the affected muscles derive their nerves; but it is not unreasonable to infer, that a highly oxygenated state of the blood will impart tone directly to the muscular fibre, that an opposite state of the blood will impair the tone of this fibre, and that the accumulation of acid, acrid or irritating elements or materials in the blood, occasioned by interrupted excretion or otherwise, will sometimes cause not only exalted or morbid contractions of muscular parts, but also irritation and vascular excitement of the substance and membranes of the nervous centres. If the vascular excitement go on to the usual condition and consequences of inflammatory action, these changes will rarely be limited, although more manifest in one part than in another, for the exciting pathological cause is general, being present in the blood, and implicates both the nervous structures and their membranes; whereas the more common exciting causes of inflammation chiefly act locally, and affect a portion only of these structures, although often extending more or less to adjoining parts.

53. V. Causes. — *A. Predisposing causes.* — The several forms of tetanus are more frequent and more fatal in the male, than in the female sex. This is partly owing to greater exposure of the former to the exciting causes, especially to injuries, accidents, and wounds. Of the influence of temperament in favouring the occurrence of the disease, we have no certain knowledge; but probably the nervous and irritable temperaments are most prone to it. There is no doubt of the much greater liability of the negro race to every form of tetanus or trismus, than of the white race. Climate and locality have a marked influence in predisposing the frame to a tetanic seizure. This is evinced by the much greater frequency of the malady in hot, than in temperate climates, and in humid and malarious localities, than in dry situations. Disorders of the digestive organs, especially the retention of morbid secretions and excretions in the digestive canal, the existence of intestinal worms, the failure or arrest of the depurating functions, and the consequent contamination of the circulating fluids, are amongst the most frequent causes of predisposition. Bodily fatigue, harassing duties and occupations, excessive muscular exertions, and irregularities of diet or unwholesome food, are also causes of predisposition. The catamenial period, parturition, and abortions also favour the occurrence of the disease in females.

54. *B. The exciting causes,* in temperate climates, are chiefly injuries and surgical operations. Punctures and lacerations of fascia, tendons, and nerves; lacerations and ligatures of nerves; and injuries of the extremities, especially of the hands and feet, are the most frequent causes; but wounds in any situation or part of the body, and of every kind and grade, from the sting of a bee or wasp, or the abrasion of the cuticle, to the amputation of a limb, may produce tetanus. A cleanly incised wound is much less likely to occasion this disease than a puncture or laceration. But, although these injuries are chief causes of the attack, the influences of the predisposing causes, and of those which are mainly concerned in producing the idiopathic form of the disease, in concurring to develope the malady, should not be overlooked. The causes which thus give rise to the idiopathic state of the malady, and which so often concur with injuries in developing the symptomatic form are, vicissitudes of temperature, exposure to the heat of the sun, more particularly to the sun's rays, and soon afterwards to the chills, dews, and cold of night; sleeping on the ground, especially when exposed to the night dews or moon's rays; exposure to currents of air, or to cold and wet in any way; drinking cold water, or other cold beverages, when the body is perspiring; imprudent cold bathing; sleeping in confined and ill-ventilated apartments; breathing a contaminated or a miasmatous atmosphere; and such laborious occupations as making trenches, digging clayey soils, &c. Whilst these concur with, or aid injuries or wounds, in giving rise to tetanus, they frequently of themselves occasion the disease, especially in hot climates, and in the dark races, more particularly the negro race, by arresting the eliminating processes, and by favouring the accumulation of morbid materials in the blood, which enter into new combinations, and irritate the nervous centres and membranes, and the muscular structures themselves, both directly and indirectly, by means of the nerves. Owing to a stricter attention in preventing these predisposing and concurring causes, and to the adoption of a more wholesome diet and regimen, the several forms of tetanus are now much less frequent than they were many years ago, more especially the traumatic or symptomatic form. Tetanus may be produced by some poisons, particularly by nux vomica, and its preparations (See Art. Poisons §§ 364—381, *et pluries*).

55. As I shall have to show hereafter, certain of the exciting causes seem to act more directly on the spinal medulla than others, whilst many of these causes occasion a state of the most distressing irritation, transmitted through the medium of the ganglial system, or of the sentient nerves, or even through the media of both, to the cerebro-spinal centres, and thence reflected on the muscles of voluntary motion. Thus worms in the digestive canal, not only predispose to attacks of traumatic tetanus, but also directly occasion the idiopathic form of the malady. That these parasites are no infrequent cause of tetanus has been insisted upon by Avicenna, Schenck, Hillary, Bisset, Rush, Chalmers, Michaëlis, Rahn, Zulatti, and De Haen; and not by worms only may the disease be thus occasioned, but also by whatever inordinately irritates the intestinal canal, as the retention of the meconium, or the use of drastic purgatives, in infants. I have seen it caused by internal strangulation of the bowels, the primary lesion being accurately ascertained only after death. A temporary state of tetanus has even been produced by the passage of gall-stones, as was shown by a case which lately came under my care, emprosthotonos, of many hours' duration, having been thereby occasioned, with the slowness of the pulse which usually attends this form of biliary obstruction, the attack having been not only severe, but also protracted. Tulpius has recorded an instance of the disease having been

occasioned by calculi in the kidneys; and I have observed the sufferings produced by the passage of calculi along the ureters, accompanied by spasms so general, so continued, and so severe, as closely to approach the tetanic state.

56. Several of the causes are very rarely productive of the malady, as caries of the vertebræ; whilst others which had more frequently occasioned it, are fortunately not so often observed now as in former days. Tetanus not seldom followed a recourse to torture, as torture was practiced either by civil authorities or by pseudo-religious inquisitions, or by military and naval commanders; but whether the wretched result proceeded from the excessive pain thereby produced, or by the irritation excited in the tissues — the integuments, the nerves, the muscular or the tendinous fibres — of the parts which sustained the injury, cannot be readily determined. HARDER says, that he has seen it follow pain only; but it may justly be admitted, that excessive pain may have predisposed the system to be affected by the irritation more permanently developed in the seat of torture. That the disease may follow either burns or scalds has been admitted by many writers, and has been shown by SMITH, FIZEAU and others; and that it may be caused by fright or terror has been proved by RIEDLIN, PIDERET, HANSA, BIERLING and LATOUR. DE HAEN says that he has seen it produced by retrocedent gout; and probably the *materies morbi* of gout in the blood had so excited the spinal medulla and membranes as to develope a state of morbid or continued contraction of the muscles, amounting to idiopathic tetanus. WRIGHT and other writers have insisted much upon the influence of insolation in warm climates, or in warm seasons in temperate climates, in occasioning tetanus, and with much justice, as inter-tropical physicians will admit; and no less just and important is the fact shown by AVICENNA, and adverted to by many since the days of the celebrated Arab, that sleeping on the ground, especially after exposure to the sun's says, or whilst exposed to the night dews, or to the moon's beams, is a most influential cause of idiopathic tetanus, and of the development of the malady after injuries, wounds, &c.

57. *C.* The *Formative period* of tetanus, or the time which elapses from exposure to the causes until the commencement of the attack, is a matter of some importance, as respects the elucidation of the manner in which the causes act, and the employment of measures calculated to prevent the development of their effects. The duration of this interval is most various — from an hour or two to fourteen days, — most frequently, in cases of injury, from the fourth to the fourteenth day. In the returns furnished by Sir J. MACGRIGOR, the interval never exceeded three weeks. Sir G. BLANE mentions four weeks as the longest period. Sir B. BRODIE observed the disease to commence generally in the second week. MR. CURLING refers to an instance recorded by Mr. WARD, of the occurrence of the malady ten weeks after a burn in the axilla. May not some other cause or causes have occurred in this interval?

58. It has been noticed by Mr. CURLING and others, that the longer the interval between the receipt of the injury and the appearance of the symptoms, the less acute and dangerous is the disease. In thirteen cases the symytoms did not commence until three weeks after the wounds, and only four of these were fatal; and of seven cases in which the symptoms did not appear until a later period, or about four weeks, only two terminated fatally. The more rapidly the disease follows its exciting cause, the more acute and fatal does it prove, in both the idiopathic and the symptomatic form.

59. *D. The state of the injury* or wound at the commencement of the disease, is a subject of interest. Dr. RUSH remarked, that there is an absence of inflammation or free suppuration from the wounds causing tetanus. This generally appears to be the case. The injury either seems to be healing, or is quite healed, and even forgotten, when the disease commences. In some instances a feeling of irritation is referred to the injury or cicatrix; and in others a cause of irritation, of a material or palpable nature, is detected in one or the other, or is found to affect a branch or filament of nerve. In others no such feeling or cause apparently exists. If a healthy suppuration have existed in the wound, it is usually suspended, and is followed by an ichorous, or scanty sanious discharge, just before the accession of the spasms of the muscles of the jaws and neck and the difficulty of deglutition, or contemporaneously with the accession of the premonitory symptoms mentioned above (§ 4.).

60. VI. THE PROGNOSIS.—The *issue* of tetanus varies with the causes, and with the form which the disease assumes. A fatal result is most frequent in the traumatic form. It is less frequent in the idiopathic form, and much less frequent in the sub-acute, whether idiopathic or symptomatic, or when the malady is prolonged beyond the ninth or tenth day. Much, however, depends not only upon the exciting or efficient cause, but also upon the influence of concurring causes, as exposure to cold and wet, to malaria, or to an impure or often respired air, and the presence of intestinal worms, either, or all, of these tending remarkably to increase the mortality of the traumatic form. The concurrence of malaria or other impurities of the air, with exposure to cold, also greatly increases the fatality of the idiopathic states of the malady. Recovery very rarely takes place if the pulse rise above 110, in the intervals between the exacerbations on the third day, especially in the traumatic form; still more rarely, if it reach 120 on that day; and no hopes may be entertained, if the pulse in that form reaches this latter frequency on the second day, or at an earlier period. Dr. PARRY thought that, if the pulse of an adult be under 110 on the fourth day, the prognosis is favourable; and if 120 or upwards, unfavourable; but cases frequently terminate fatally on the third, fourth, or fifth day, and yet the pulse, in the intervals between the paroxysms, has not risen above 100, or 110, or even, according to some writers, above 80 or 90, although this latter state of the pulse, in acutely fatal cases, does not quite agree with my observation. Dr. DRUITT has very truly and ably stated that, "as a general rule, the prognosis is *favourable*, if the complaint is partial, — if it does not affect the muscles of the glottis, — if it has lasted some days, without materially increasing in severity, — if it is sensibly mitigated by the remedies employed, — if the pulse is not much accelerated, — if the patient sleeps, — and if he has been subject to it before, in an intermittent

form. On the other hand, the prospect will be *unfavourable*, if the spasms continue to increase in severity, and especially if they affect the muscles of the glottis;" and I would add, or if they extend to the diaphragm and other muscles of respiration; and if the disease be very acute and the pulse very frequent on the second day.

61. VII. PATHOLOGICAL INFERENCES and REMARKS.—*a*. That a predisposition, original or acquired, exists in some constitutions to be affected by tetanus, when the exciting causes, by their nature or their concurrence, are brought into operation; that this predisposition is most evident in its original state, in the negro race, and in the darker races; and that males appear to be more susceptible of this malady than females.

62. *b*. That depressed states of organic nervous power, connected with nervous susceptibility and with increased irritability, seem to favour the occurrence of an attack of tetanus; and that, still more especially, the presence of worms in the digestive canal, disorders of the digestive and intestinal functions, intertropical or warm and miasmatous localities, or otherwise contaminated states of air, and the arrest of the excreting processes, further tend to favour the appearance of the malady, by accumulating excrementitious materials in the blood, and aid the operation of the exciting causes enumerated above (§§ 54, *et seq.*).

63. *c*. That the lesions of the nervous centres of animal life, on which tetanus has generally been supposed to depend may be: — 1st, that of erythism, or of irritation, in which vascular injection and organic lesion are either not seen, or not manifested to any considerable amount, or so as to be admitted as inflammatory;—2dly. Or, that of increased vascularity and the changes generally viewed as constituting inflammation, or consequent upon it; — 3dly. Or, any change intermediate between the extremes of these states — the minima of the former, and the maxima of the latter — may be inferred to exist in cases of the several forms of this disease.

64. *d*. That similar lesions, in their nature and amount, to those just stated may exist in the sentient or centripetal nerves, or in the ganglial nerves, which are the media by which the irritation is transmitted from its primary seat to the spinal medulla and central parts of the base of the brain, although lesions in these communicating nerves are not easily ascertained, traced or rendered apparent after death; or they may be such as are compatible only with the living state, and disappear soon after dissolution.

65. *e*. That any irritation at the periphery of the nervous sphere may be propagated by sentient nerves to that part of the nervous centres with which the part irritated is most intimately connected or related, and be reflected thence upon muscular parts, through the motor nerves which are most intimately connected with those portions of the nervous centres to which the irritation is transmitted.*

66. *f*. That the irritation of the muscular structures themselves. directly produced by the accumulation of morbid and irritating materials — acid or saline — in the blood, may induce a more or less continued state of spasm of the muscles, and the existence of these materials in the blood, may perpetuate this state and superinduce further changes in the nervous centres and in their membranes, this state of the blood being produced as above noticed (§ 52.).

67. *g*. That the irritation thus excited may be perpetuated or continued to the extinction of life by asphyxia or by vital exhaustion, without the changes actually constituting inflammation having been developed — at least to an amount admitting of their permanent manifestation or undoubted existence after death.

68. *h*. That, although this (§ 67.) may be the case, especially in the traumatic form of tetanus, and more especially when the ganglial system, which is so intimately connected with the existence of irritability in all animals, is brought within the sphere of morbid action, yet inflammation and its usual consequences actually does sometimes take place, but not so frequently and evidently in the traumatic, as in the idiopathic malady.

69. *i*. That the inflammatory changes observed particularly in the idiopathic form, as when occasioned by insolation and by subsequent exposure to cold or the night dews, or by sleeping on the ground, &c., may be early produced, the tetanic phenomena being merely the manifestation of the early inflammatory state and changes in the membranes or substance, or in both, of the spinal medulla, extending often to, if not originating in, the medulla oblongata and the central parts of the base of the brain; and that the changes, whether inflammatory or merely irritative and incapable of demonstration, which first take place in the nervous centres of animal life, should be looked for in the parts most intimately connected with the origins of the nerves supplying the muscles of the pharynx, lower jaw, throat, and neck; these changes, as they extend along the membranes of the medulla oblongata and chord, extending the sphere and the severity of the malady.

70. *k*. That, in these cases (§ 69.), according to my observation, the pain which is commonly felt in the occiput, and in the cervical and dorsal regions of the spine, with the throwing backwards of the head, &c., in addition to the symptoms pathognomonic of tetanus, early declare the seat and nature of the disease — irritation or inflammation of the parts now mentioned (§ 69.).

71. *l*. That, in cases which arise from irritation in some distant part, transmitted to nervous centres and reflected thence upon contractile structures, and in which inflammatory action is either absent, or its existence is problematical at an early period of the malady at least, we can no infer, agreeably with what we know to take place in the animal œconomy, that inordinate or continued contraction of muscles can exist, without an increased demand being made upon the circulation supplying the nervous centres which actuate these muscles; and hence we may conclude that increased vascularity, or even the earlier states of inflammation, of these centres and of these membranes may be the necessary consequences of the continued and inordinate muscular action constituting the disease; the augmented determination of blood thus directed to these nervous centres

---

* This view is identical with that stated with reference to the pathology of CHOLERA, CHOREA, and CONVULSIONS, articles which were written more than three years, and published in 1832, or about two years, before Dr. M. HALL's earliest writings on the reflex *function*.

tending to the perpetuation and the extension of hte muscular contractions, and thereby to the more or less rapid extinction of life.

72. *m*. That, notwithstanding this condition of the nervous centres of animal life, whether primary or superinduced, it is most probable, that the contractions would not become so persistent, or the spasms so severe and frequent, if the ganglial system preserved a normal state of function, or was free from irritation or vascular excitement.

73. *n*. Inferring, as stated above (§§ 63, *et seq.*). that tetanus may depend upon, or be connected with, one or other of three pathological states of the nervous centres of animal life, namely, — 1st. Upon inflammatory action of these centres or of their membranes, especially in the idiopathic form of tetanus,—2nd. Upon inflammatory action superinduced upon irritation transmitted from the periphery of the sentient nerves to these centres, or from ganglial nerves to these centres, and thence reflected on contractile structures, — and, 3rd. Upon irritation thus transmitted and thus reflected, without sufficient proof of inflammation, — it should become an object to ascertain with all possible accuracy, to which of these pathological states the case belongs to which we are called to administer relief; for, upon the inferred pathological condition, the indications and the plans of cure should be based.

74. *o*. Many of the changes which are presented by the lungs, the heart, the blood, and even by the liver and digestive mucous surface, are manifestly results of the mode of death. Those seen in the pharynx and glottis are evidently caused by spasms of those parts, consequent on the irritation or inflammation, or both, existing in the medulla oblongata and its vicinity, and upper portions of the spinal medulla, or their membranes. Yet other morbid appearances may exist in different portions of the digestive canal, or in one or other of the urinary or genital organs, which cannot be viewed as the results either of the malady or of the mode of death; but which may be considered as being either sources of irritation, or as concurring aids to irritation, or merely as accidental and unimportant changes: if they be viewed in the former light, it becomes important to ascertain how far they can be connected with the early or premonitory symptoms, and to determine the manner in which the functions of the organs in which they were seated, had been discharged.

75. *p*. That, when tetanus follows irritation or injury in some peripheral part of the nervous system, the division of nerves or parts between the seat or cause of irritation and the nervous centres most frequently fails of arresting the disease; such failures evincing the superinduction and extension of the irritation, or other morbid condition constituting the malady, to the nervous centres of animal life, and probably also to the organic or ganglial system, to which I imputed irritability in its normal manifestations very many years ago, and more recently in this work. (See Arts. IRRITABILITY and IRRITATION).

76. VIII. TREATMENT.—A slight experience of the different modifications of tetanus, more especially of the idiopathic, symptomatic, and infantile forms, is sufficient to show the justice of the distinctions which I have endeavoured to establish, between what may be considered as the inflammatory and the irritative states of the malady. But as either state does not exist simply or unassociated — as one condition is accompanied with more or less of the other — as the irritative often sooner or later becomes inflammatory, or the former state frequently induces the latter, the difficulty of determining in practice how far the one state may exist independently of the other is remarkably great. Unfortunately a simply inflammatory state of either the membranes, or the substance of the central parts of the base of the brain and medulla, or of both the membranes and substance of these parts, is seldom so manifested as to admit of a distinct recognition, the very phenomena which it sympathetically produces either masking its presence, or throwing doubts on its existence. Besides, irritation is so nearly allied to inflammation, even when it exists simply, and so often excites the inflammatory state, by eliciting vascular determination and injection — " ubi irritatio, ibi fluxus" — that we can hope only to reach an amount of accuracy which may not altogether be deserving of being considered erroneous. If the difficulty of ascertaining pathological conditions, upon which all rational indications of cure should be based, be so great in this malady as not to have hitherto been overcome, can it be a matter of surprise that the means which have been resorted to, both by physicians and by surgeons, in its treatment, have been most opposite in their effects, the most different in their natures, and in every respect most empirical and uncertain? In this state of our knowledge it would be better to leave Nature to her unaided efforts, to observe closely and accurately what is the true procession of changes and of their manifestations, and to ascertain the seats and the extent of lesion as soon after death as may be attempted with propriety.

77. I have contended above, more strenuously perhaps than any previous writer, for the inflammatory character of this malady, especially in the idiopathic form. But admitting the existence of this character, as manifested by the changes observed after death, the following questions remain to be determined, namely, Is the inflammatory state necessarily or always evident to the close observer during the life of the patient when it actually exists? and, if it be evident, Is it most successfully treated by the usual means resorted to, when combating the sthenic form of inflammatory action? — 1st. As respects the former question, it may be said, that inflammation of either the substance or the membranes of the spinal medulla, or of the medulla oblongata, or parts in the vicinity, is often ascertained with great difficulty. This is apparent from what I have said when treating of spinal inflammations (see art. SPINAL CHORD, &c., §§ 137, *et pluries*); and there I have viewed them as they are usually presented to both physicians and surgeons in the course of practice — as commonly limited to a portion only of either the membranes or substance of the chord, or as advancing along them gradually, and attacking successively adjoining portions. But, when the inflammatory action of these parts extends rapidly, or takes place almost co-ëtaneously, the effects upon contractile structures are quickly and extensively manifested. Whether, therefore, it be irritation or inflammation which

is produced in the spinal medulla and its membranes, or irritation quickly inducing a certain amount of vascular injection or inflammation, or merely an exalted polarity of the spinal chord, as contended for by K. SPRENGEL, there is reason to infer, that the morbid condition is at first limited in extent, although advancing rapidly, and that it commences in the more immediate vicinity of the origins of the nerves supplying the muscles of the pharynx, lower jaw, and neck. When pain is felt in the cervical region of the chord, extending either upwards to the occiput or downwards to the dorsal and lumbar regions, when the sensibility of the surfaces, whose nerves are connected with those parts of the nervous centres, is unusually increased, or when any stimulus acts upon the muscles connected with these parts, so as to occasion spasm or distress, as when attempting to swallow, it may then be inferred, that a morbid action, usually termed inflammatory, is really present in the membranes or structure of these parts, although pain and other symptoms may not be exasperated by pressure on that portion of the spine where inflammation of the chord or its membranes is indicated; pressure no further influencing the pain than it would if it were made upon some part of the cranium when the brain is similarly affected.

78. 2nd. Admitting the presence of inflammation in the spinal medulla, or central parts of the base of the brain, or their membranes, in many, if not in the great majority of, cases of tetanus, either at an early or in an advanced stage, or consecutively upon transmitted irritation, the success of such means as are usually employed against inflammation still remains questionable. We know that the term inflammation has been applied to very different states of vascular injection, as I have shown when treating of inflammation, and that these states differ as to the current through the capillaries, as to the power or tone which these vessels manifest, as to the products or fluids which are exuded from them during these states, and as to the extension of the morbid action or condition to continuous or contiguous tissues. Hence, even when the first question is admitted in the affirmative, we must have recourse to the results of an enlightened experience for our answers to the second: and these answers only can be given, so as to be satisfactory, by referring to the effects of such means as are most successful in removing changes commonly considered as, and denominated inflammatory. But it should not be overlooked, that it has been most satisfactorily shown, that these changes are so different in their local characters, in their constitutional relations, and in their tendencies and results, as to require for their successful issues very different and often opposite means of cure; the differences being occasioned chiefly by the varying grades of organic nervous power, and by the presence of irritating or injurious excrementitious materials in the blood (§ 52.). These facts have been fully illustrated when treating of the several forms, varieties, and modifications of *Inflammation* in the different organs and tissues; and what has been proved and admitted of inflammation generically, and of the special manifestations of it in these organs and tissues, may be extended to inflammation in those parts of the substance and membranes of the nervous centres to which the disease has been now chiefly referred.

79. But, it should not be overlooked, that whilst the fully developed malady may be attributed to an inflammatory state of these parts, induced by transmitted irritation, the primary morbid condition, especially in the traumatic or symptomatic form of the malady, — the irritation existing, whether manifested or not, in the seat of injury, propagating itself to the nervous centres, there developing morbid action, and perpetuating reflex muscular contraction,— should be attempted to be removed or counteracted by the most efficient and appropriate means. Whilst the local or primary irritation exists, or its transmission along centripetal nerves is not interrupted or prevented, the procession of irritation to inflammatory action, and the extension of this action along the membranes, with the reflected muscular contractions, are thereby promoted, and the morbid consequences — the tetanic contractions and spasms — necessarily aggravated. Therefore, at all periods of the malady, but as early in the treatment as possible, means should be employed, in *the traumatic form* of the malady, *to arrest the transmission of irritation from the seat of injury to the nervous centres, or to allay irritation in this seat.*

80. *A.* THE LOCAL TREATMENT of traumatic tetanus should therefore be as early as possible determined upon; the means being such as are most suitable to the nature of the injury. To obtain the end now stated — 1st. Amputation or excision of the wounded part;—2nd. Division of the nerves proceeding from the seat of injury;—3rd. The application of agents calculated to procure a healthy action or a free suppuration in the injured parts, — and 4th. A recourse to soothing or anodyne applications to these parts, and in the course of the nerves proceeding from them, have been severally recommended, and have been found of service in some cases, and inefficacious in others. It is obvious that, when the symptoms of tetanus, and even when those of its first stage, trismus, have appeared, the pathological changes in the nervous centres and their membranes have already commenced, although they may not be fully developed; and that the removal of the remote irritation which produced these changes may not then be influential in subduing them. Nevertheless, the removal of the cause may render the effects either more mild or more controllable by treatment, — may prevent the effects from reaching that amount which the continuance of the cause might develope.

81. *a.* Instances of recovery from acute traumatic tetanus, after *amputation* had been employed in order to arrest the attack, have been recorded by LARREY, VALENTIN, WHITE, HOWSHIP, and others; but recourse to it has also failed with many. Mr. CURLING states, that it was performed in eleven of the cases in the table which he has given, and of these seven were cured. In most of these, however, the operation was resorted to before the symptoms were fully developed, at which time only should hopes of success from it be entertained. It is inadmissible in sub-acute tetanus, unless the condition of the injury be such as demands the operation independently of the spasms; for most of the cases of this form recover, often notwithstanding the treatment which has been

adopted. Mr. Curling very justly remarks that amputation is justifiable only after a severe injury of the extremities, immediately that there is the slightest indication of spasm; for, if delayed until the disease is more advanced, instead of proving beneficial, it will rather aggravate the symptoms and render the constitution less able to sustain the exhausting effects of the spasms.

82. *b. Division of the nerves*, in order to arrest the transmission of the irritation from the injured part, and even of the *tendons* and *aponeuroses*, when these are lacerated or injured, has been advised and practised in some cases with marked success by Schmucker, Hicks, Delaroche, Murray, Fournier, Stütz, Larrey, and some others. When this operation can be performed so completely as to comprise all or the chief nerves proceeding from an injured part, it should not be neglected, nor delayed until the disease is fully evolved. It is in every respect to be preferred to amputation. Dr. Pennock has advised the application of ligatures or cupping-glasses, in order to paralyse the nerves, when a complete division of them cannot be effected, as previously recommended for poisoned wounds. In cases of cutaneous or superficial injuries, &c., these means may be resorted to.

83. *c. Incisions* made into the seat of injury, and *applications* which may excite a free suppuration in it, have been recommended by Rush, Valentin, Mercier, Campet, Larrey, Parant, and many others. The actual or the potential *cautery* has been advised by some, with this intention; and a free opening into the seat of injury, or reopening of the cicatrix, or incisions into it, and the application of various substances, with the view of exciting healthy action, have been recommended by others. In one case, I directed the injured part to be freely incised, soon after the occurrence of spasms of the muscles of the wounded limb, and the incision to be filled with lint soaked in equal parts of tincture of opium and spirits of turpentine, the same substances being also applied as an embrocation, on flannel, in the course of the nerves proceeding from the part; but, as the treatment about to be noticed was employed at the same time, the share which these means had in the recovery of the patient is not very manifest; the local symptoms, however, appeared to be much alleviated by them.

84. *d. Soothing*, *emollient*, and *anodyne* applications were advised by Hippocrates, Celsus, Cælius Aurelianus, and by many of the moderns, to the injured part; they may be employed either immediately or after the division of nerves or the incisions already noticed. These means have not been restricted to the part, but have likewise been applied in the course of the nerves proceeding from it. The agents which have been thus employed by the more recent writers consist chiefly of moist heat, anodyne poultices, fomentations, or embrocations; applications containing either opiates, or conium, or belladonna, &c. It has also been recommended by Cerioli, Lembert, and others, to remove the cuticle from the parts in the vicinity of, or above the seat of injury, and to apply either of the preparations of *morphia* to the denuded surface. It is obvious that these, or similar means, can be of use only early in the disease, and as aids to other rational measures.

85. *e.* Whilst *these local means* are more or less appropriate to traumatic or symptomatic tetanus, and chiefly to the acute form at a very early stage of the attack, and are useful aids to the treatment which the pathology of the disease will suggest, the measures about to be passed under review *are equally suitable to all the forms of the malady*, duly adapting them, however, in respect of amount, combination, and succession, to the severity and peculiar features of individual cases. It should not be supposed that all cases which recover, especially those which I have denominated as sub-acute, and more particularly such as are symptomatic of, or associated with, other diseases, as with hysteria, or with epilepsy, or even with the effects of malaria, as insisted upon above (§ 22.), are really cured by the means which have been employed. Nature in many of these cases asserts her own prerogative, and carries it above the many and incongruous agents too often irrationally, empirically, and injuriously resorted to. If we consider the diverse and even opposite nature of the measures which have been prescribed for this malady, their apparent success in some instances and their failure in others, and their employment in different states of the disease, with little regard to the modes of their operation in relation to pathological conditions, we necessarily must infer that recovery has sometimes taken place, notwithstanding their use, and not by their aid.

86. *B.* The external means recommended by writers are almost as numerous as those prescribed internally, and whilst they have been used as adjuvants by some, they have been more entirely confided in by others. — *a.* Not the least important of these are the *affusion of cold water* and the *cold bath*. The former was prescribed by Hippocrates, but he directed the patient to be afterwards wrapped in warm coverings. The cold affusion was also adopted by Avicenna, Schenck, Kite, Rush, Wright, Tallmann, and Currie, for this disease; and the cold bath by Cochrane, Harris, Mosely, and the writers now mentioned. Celsus considered the cold bath to be injurious. Fischer advised it, opium having been given internally. In the cases in which opium has been taken in large or frequent doses, the cold bath, and more especially the cold affusion on the head and cervical spine, are much less hazardous, if not beneficial, in this disease than when they are resorted to under other circumstances. Both the cold affusion and the cold bath are not without some degree of risk, if the shock produced by either be too sudden or too severe for the amount of vital power. But when judiciously employed, and the effects carefully watched, and aided by appropriate internal remedies, they may, especially the cold affusions, prove most influential means of cure, more particularly in the idiopathic form of the malady. Many instances have been recorded of recovery from acute tetanus, by means of cold applied in either of these modes, or in some other way. The changes found on dissection after fatal poisoning by *nux vomica* and *strychnine* are the same, as respects the spinal medulla, the central parts of the base of the brain, the cerebellum, and their membranes, as those observed in fatal cases of tetanus; and the treatment found most successful in poisoning by these substances is generally appropriate in acute tetanus. (See *art.* Poisons, §§ 364—

381.) M. GUÉRIN DE MAMERS states, that the cold affusion arrests the tetanic paroxysms produced in animals by nux vomica. The application of cold lotions, or of pounded ice, to the occiput and nape of the neck, whenever or as long as the temperature of these parts is above the natural standard, has not hitherto received the attention it deserves as appropriate means in this disease.

87. *b. Warm baths* and *Vapour baths.* The former were recommended by MARCARD and BEHN. Sir J. MACGRIGOR found them to produce momentary relief only. HILLARY and DE HAEN have stated that instantaneous death has sometimes followed their use. This result may have arisen from their temperature having been too high, especially when the patient was first immersed. Warm baths are the safest, if not the most beneficial, when their temperature is at first from 85° to 90°, and gradually raised to 96° or 98°. They have little influence on the acute form of the malady; but they are often of service in the sub-acute, and during convalescence. BEHRENDS, MURSINNA, STÜTZ, and MARCUS prescribed warm baths, containing alkalies and aromatics; and ANDERSON recommended tobacco to be infused in the bath, and after the operation of purgatives, wine to be freely exhibited. Warm baths have been employed chiefly in connection with the internal use of stimulants, tonics, and antispasmodics. Dr. MARSH has recorded three cases, in which *vapour baths*, at a low temperature, were employed for many hours in succession. Two of the three cases recovered; but they were of the sub-acute form. These baths have been also prescribed by several Continental physicians; but with no advantage in the acute form of tetanus.

88. *c. Emollient applications* over the spine in this disease were noticed by HIPPOCRATES, CELSUS, CÆLIUS AURELIANUS, and others; and these applications either consisted of vegetable oils, or were aided by *oleaginous frictions* over the general surface of the body. That they may have appeared of some service in sub-acute cases may be admitted; but that they were in any way of service in the acute admits of doubt. *Frictions* along the spine were advised by CELSUS and many others.

89. *d. Rubefacient and oleaginous Liniments and Embrocations*, applied over the spine, were employed in tetanus by ARETÆUS, AVICENNA, RULAND, DE HAEN, and STÜTZ; but the benefit to be derived from them in the acute form was doubtful, although they may have proved of service in the sub-acute. I have prescribed certain of the *Liniments* contained in the Appendix (*See Form.* 295—297. 307. 311.) with apparent advantage, or equal parts of the turpentine and of the compound camphor liniments of the London Pharmacopœia, with a little Cajuput oil, when applied constantly along the spine, in the form of an embrocation, by means of flannel or spongio-piline. — *Sinapisms* and *Blisters* over the spine were recommended by RUSH, HUNTER, and LATOUR; but CHALMERS contends that they produce an injurious effect. The application of the *actual cautery* to the neck is mentioned by CELSUS; but it has not received the sanction of modern writers.

90. C. CONSTITUTIONAL AND INTERNAL MEANS. — *a. Antiphlogistic measures* have been advised by many writers, and more or less censured by others, in this disease. But the selection of these measures, the extent to which they may be carried, and their adaptation to the peculiarities of individual cases, are of the utmost importance, rendering them either beneficial or the reverse. — (*a.*) Of these means the most dangerous, and yet often the most beneficial, is *bloodletting*. For, if prescribed in cases where debility and irritability are very manifest, where the disease is far advanced, where the pulse is very rapid between the paroxysms, and where the disease follows an injury, bleeding, especially from a vein or to any considerable amount, is more frequently injurious than beneficial. The evidence in its favour is extremely contradictory. It has been recommended by ARETÆUS, CELSUS, PAULUS ÆGINETA, FORESTUS, HILLARY, PUJOL, BISSET, and many others; and its repetition, even oftener than once, has been resorted to by COXE, GARDANE, GUTHRIE, EARLE, &c.; but the results have not always been satisfactory. FLAJANINI states that he has seen death immediately follow bloodletting; whilst LISFRANC says, that it has been carried to an enormous extent and been followed by recovery. Mr. CURLING is not in favour of its adoption, unless early in the disease, and when the attack is decidedly inflammatory. In this, as well as in other maladies, the physician will be guided by a variety of circumstances. The appearances on dissection seem to favour the adoption of bloodletting, yet these appearances, if not produced, may be heightened, by the disease; and, even admitting them to have existed from the commencement, experience has shown, that inflammations of the spinal medulla, or of its membranes, are not so successsfully attacked by bloodletting, as many other inflammations. When the disease is idiopathic; the patient young, robust, and plethoric; the pulse full, strong, and not very frequent or much above 100 between the paroxysms; and the disease is not far advanced, and especially if pain is complained of in the occiput and cervical region; then bleeding by a number of *leeches* applied in these situations, or *cupping* as advised by CELSUS and PAULUS ÆGINETA, appears to be indicated. In the circumstances, also, just mentioned, not only leeches or cupping along the spine, but also venæsection, may be practised, and even repeated, according to the effects produced. In more doubtful states, *dry cupping* along the spine may be tried. *Arteriotomy* has been recommended by VOGEL; and several writers have considered, with much justice, that, when bloodletting is indicated, it should be carried to a full extent at once, and not repeated to a small amount at intervals. There can be no doubt that, in all spasmodic and convulsive maladies, however inflammatory the appearances may appear after death, or however accelerated or excited the circulation may seem during life, bloodletting, especially venæsection, is a hazardous remedy; and, although sometimes required in a decided manner, particularly in the circumstances and in the way just stated, it requires the utmost caution and discrimination. When it is clearly indicated, the action of other suitable remedies is promoted by it.

91. (*b.*) *Purgatives* are essentially requisite in tetanus and trismus; but, in order to obtain

satisfactory results from them, they should be given early and decidedly, and selected judiciously. Calomel with the compound extract of colocynth, or with jalap, or scammony, or camboge, may be prescribed in such doses as will produce, as advised by Forestus and Hamilton, copious evacuations. Moseley directed the cathartics to be conjoined with cinchona or other tonics. These, especially the more bitter tonics, generally render the operation of purgatives more certain. In the few cases I have seen, I have prescribed, at first, full doses of calomel with camphor; and, some hours afterwards, the spirits of turpentine with castor oil, the action of these having been promoted by enemata containing these oils and some common salt. The frequency of worms in the digestive canal of patients attacked with either idiopathic or traumatic tetanus, has induced me to prefer these means, and to give them in large or repeated doses early and according to the circumstances of the case. The oil of turpentine, when judiciously prescribed in this disease, is not only an energetic anthelmintic and purgative, but also the most certain antiphlogistic and antispasmodic remedy we possess. After the bowels have been freely evacuated by its aid, or by a combination of it with other cathartics, it may be given internally at various intervals, either on the surface of an aromatic water, or in the form of an electuary made with honey and powdered liquorice-root; and may be administered in enemata, or applied along the spine in the form of embrocation (§ 89.).

92. Where there is reason to infer that the disease is favoured, or in any degree occasioned by the presence of uneliminated acid, acrid or excrementitious materials in the blood, the action of the excreting viscera should be excited by means of these and other purgatives, by diuretics conjoined with or alternated with these, or by combining cathartics and diuretics with large doses of the alkaline carbonates, or of the chlorate of potash, or with magnesia and sulphur in full and repeated doses, so as not only to excite the several emunctories, but to change the state of the blood, and to counteract the injurious action of the morbid materials by combining with them and neutralizing their influence and effects.

93 (*c.*) *Mercurials*, internally and externally, have been very frequently prescribed in all the forms of tetanus, as purgatives, as alteratives, and as antiphlogistics, and have received the sanction of Manget, Donald Monro, Mease, Kite, Clark, Ecker, and others; and calomel, the bichloride of mercury, and the oxides, have been severally employed, in order to produce these effects. Calomel, given in full doses, alone or with other medicines, early in the disease, and as a cologogue purgative, is generally of use. But no confidence can be placed in it, or in any other mercurial, as a remedy for tetanus, especially the traumatic form. Mercurials were formerly much employed in the West Indies as purgatives and alteratives for the cure of idiopathic tetanus, but even when ptyalism has been produced by them, no alleviation of the disease has resulted, as shown by MacGrigor, Wells, Thomson, Carlisle, and Curling, tetanus even having occurred in persons during mercureal salivation; and the malady appearing to have been aggravated in other cases by the production of this effect. Of twelve cases related by Mr. Howship, of tetanus consequent upon injuries, in which mercury was freely exhibited two only recovered, and in both it was conjoined with opium.

94. (*d.*) *Antimonials* are uncertain in their operation in trismus and tetanus, and are liable to the same objections as have been urged against bloodletting, but they also possess the advantages sometimes to be procured from the latter. The preparations which are most deserving a trial in this disease, are tartar emetic and James's powder. In a case of sub-acute tetanus treated by Mr. Liston, the former was given in doses of one grain every hour, and the patient was put into a warm bath thrice in the day, the bath containing in solution half an ounce of tartarised antimony (*Lancet*, 1834 and 1835, p. 581). The pulse after the baths was generally accelerated, but became much softer as soon as the copious sweating by which it was followed appeared. Mr. Woodward (*Dublin Journal of Med. Science*, July, 1835) exhibited tartarised antimony in a case of idiopathic tetanus, with the effect of depressing the pulse and diminishing the muscular rigidity. The patient was soon able to swallow, and, by persisting in this remedy, gradually recovered. Dr. Ellis administered this substance in enemata; but no sufficient experience of the results of this practice has hitherto been furnished.

95. *b. Sedatives* of various kinds have been often prescribed for all the forms of tetanus. Certain of the means already mentioned are more strictly sedative than antiplogistic, although generally prescribed with the latter intention, especially the cold affusion and antimonials. — (*a.*) *Colchicum* has been recommended for tetanus by M. Dufresnoy. Dr. W. G. Smith has employed it largely in the West Indies, and, in his opinion, with great benefit. But as he employed several other means at the same time, the amount of benefit which was really due to this powerful medicine remains doubtful (*see* § 114.).

96. (*b.*) *Tobacco* has been much employed in cases of tetanus. Mr. Curling remarks that "the earlier writers applied the *oleum tabacci* externally to the back and neck." In a work by Dr. Gardner, at the beginning of the 16th century, entitled the *Triall of Tobacco*, it is stated that "the suffumigation of tobacco, being taken, is a good remedy for the starkeness or stiffness of the neck called tetanus." Campet, who practised in the French West India Islands in the last century, prescribed tobacco injections and wine by the mouth, and detailed several cases proving the success of the practice. The use of tobacco injections in this disease has subsequently been recommended by O'Beirne, Anderson, Earle, Travers, and Curling. In most of the cases the infusion, or decoction, or smoke of tobacco was administered as enemata, twice or thrice daily; and wine or other stimuli were given by the mouth, to counteract the distressing poisonous action of the tobacco (*see art.* Poisons, §§ 523, *et seq.*). This substance is one of the most powerful agents which can be employed against tetanus. Its effects are, however, seldom lasting, and it tends very remarkably, when given late in the disease, or when the dose is strong, to depress the powers of life beyond the powers of reaction. I have perused most of

what has been written in its praise, and I can truly state, that it has often proved injurious, owing to its having been resorted to at a too advanced period of the malady, and in a too powerful form or dose; and, even in the cases where it has appeared to have been of service, its effects appeared very equivocal. In two acute cases which I attended many years ago, the infusion of tobacco was administered as an enema, contrary to my advice, by the other medical men who were also in attendance, and both cases terminated fatally, with all the symptoms of poisoning by tobacco, a few minutes after the administration of the second injection. The bodies were examined after death, and displayed the appearances described above (§§ 27, *et seq.*). The decoction or infusion has been also employed in impregnating a warm bath, into which the patients have been immersed twice or thrice in the day.

97. The use of *tobacco* in tetanus requires the utmost caution. The sensations produced by it, when the dose is too powerful, are most distressing, and, when prescribed late in the disease, are such as often fatally prostrate the powers of life. Even when less injurious, patients have expressed the sensations occasioned by it to have been so distressing, that they would rather have endured the convulsions, painful as they were; and that they would hardly be induced to submit to a repetition of the medicine. Mr. Curling, who is much more in favour of its use than I am, states that, of nineteen cases in the table, in which tobacco was employed, nine recovered. There can be no doubt that this medicine was injudiciously prescribed as to form, dose, and period of the disease, and as to other means resorted to, in some of the fatal cases; but there is as little doubt, that in some of the cases which recovered, the result was not due to this substance. When the use of it is determined upon, in an acute or traumatic case, a scruple of the leaf should be the largest quantity for an adult, infused in twelve ounces or a pint of water, and administered as an injection. The dose ought not to be larger at first, although it may afterwards be increased according to its effects. If employed at all, it should be early in the disease; and it may then be so conjoined with other agents as to promote the operation of purgatives given by the mouth. During a recourse to it, the powers of life should be supported by tonics, stimulants, and nutrients, especially by wine, ammonia, and other means about to be noticed.

98. (*c.*) *Hydrocyanic acid* was recommended by Mr. H. Ward, of Gloucester, and given in a case detailed by him, at first every half hour in cinnamon-water; and, after three hours, the spasms having then been considerably relieved, it was continued every four hours, and was taken in wine. The patient ultimately recovered. Mr. Curling states, that this medicine was employed, in small doses, in three cases, all of which were fatal. It is obvious that, in small doses, but little advantage can be expected from it, and, in large doses, it requires great caution and a close observation of its effects.

99. (*d.*) *Æthers* have been prescribed in various combinations, in the several forms of tetanus. The compound spirit of sulphuric æther, and the hydro-chloric æther, were recommended, in conjunction with other sedatives and antispasmodics; but little benefit appeared to have resulted from them in the acute cases, and in the sub-acute their effects were doubtful. Recently, frictions with the sulphuric or the hydrochloric æthers, or with chloroform, have been prescribed; and probably much of the benefit supposed to have been derived from this mode of using these substances, has been produced by the inhalation of a portion of the vapour diffused in the air, during the use of them in large quantities in this manner.* M. Morisseau, in a case of traumatic tetanus, ordered the surface of the body to be assiduously rubbed with chloroform three times in the day. This treatment was continued during five days, and was attended by a copious perspiration. On the sixth day the patient complained only of general languor and debility (*Union Médicale*, 21st June. Paris, 1851).

100. The æthers and chloroform have been employed, especially by inhalation, with apparent success, both in this country and abroad, in tetanus and trismus. Nevertheless, they severally require a much more extensive and satisfactory trial in this disease, than has as yet been given them; and this trial should be made with greater precision, and ought not to be limited to one or two modes of using them, but extended to the exhibition of them by the mouth, to the inhalation of them with the atmosphere, to frictions of the general surface with them, and to the administration of them in enemata. Even although they may not be the means which should be mainly confided in, they will generally prove excellent adjuvants, and will palliate the most urgent symptoms.

101. *c. Narcotics* have been very generally employed in the treatment of tetanus, especially of the traumatic form.—(*a.*) Of this class of medicines, the preparations of *opium* and of its ingredient *morphia*, have been most frequently prescribed. Opinions respecting the use of opium in this disease, are not only different, but even opposite. This drug is recommended in various forms of combination, by many writers: by Larrey, conjoined with camphor and nitre; by Stütz, with the fixed alkalies in large doses; by Latham, combined with ipecacuanha in the form of the pulvis ipecacuanhæ compositus; and by Marcus in frequent and increased doses. It has been prescribed by the mouth, in enemata, and in embrocations and liniments applied externally. It has also been used conjointed with other substances, as with alkalies in warm baths; and certain of its preparations, as the aqueous solution, have been injected into the veins of persons af-

---

* The following case of inflammatory idiopathic tetanus, by Dr. Tibaldi, will show the treatment employed for this form of the disease in the north of Italy:—A labourer, aged 28 years, was attacked with tetanus two days after lying on the damp ground while in a state of perspiration. In pursuance of the plan generally adopted in that country for this disease, he was bled eight times during five days, sometimes to as much as twenty ounces; and above a hundred leeches were applied to the painful parts. On the sixth day, the state of the patient being still severe, Dr. Tibaldi had the loins rubbed twice with sulphuric æther; the patient was bled a ninth time, and took half a grain of acetate of morphia. The frictions with æther allayed the spasms. The next day (the seventh) he was again bled, and an ounce of æther was rubbed over the back and neck. On the following day the patient could sit up, and was soon afterwards convalescent.

flicted with this malady. *Morphia* and its salts have likewise been prescribed, both internally and externally, in the several forms of tetanus, and not infrequently to a blistered surface, after the removal of its cuticle.

102. It is difficult, if not impossible, to form a correct or a precise opinion as to the effects of these preparations, or of the best modes of combining and administering them in this malady. Whilst several authors are favourable to the use of them, others of great experience, as Sir J. MACGRIGOR and Mr. TRAVERS, consider them, if not objectionable, at least inefficient; and some writers have given opium, either in solution or in a solid state, in so enormous doses in this disease, without any very marked effect, as to induce a belief, either that the drug has not been swallowed, or that the system is insusceptible of its action during the malady. The truth, however, is that the opium, by the excess of the dose, paralyses the vital actions of the stomach, and it is retained in this organ without change. Moreover, there is no doubt that it has often been given both improperly and injuriously, as respects the quantity, the modes of administration, and the previous treatment. None of its preparations should be prescribed until the secretions, excretions, or fæcal accumulations have been freely evacuated. Either of them which are most congruous with the other medicines prescribed may then be tried, in decided and frequent doses, by the mouth or in enemata, in conjunction with antispasmodics, aromatics, stimulants, or tonics, or with camphor or ammonia, or the fixed alkalies, oxide of zinc, oxide of bismuth, or with castor, musk, &c., or even with wine or brandy, according to circumstances, or when the evidence of morbid irritation predominates above that of inflammatory action in the nervous centres and their membranes. In this state or form of the malady, the endermic application of morphia may be prescribed, whilst other medicines, as stimulants, antispasmodics, or tonics, are liberally taken; or the fluid preparations of opium may be administered in enemata with camphor, assafœtida, spirits of turpentine, &c.

103. MM. PERCY and LAURENT (*Journ. des Progrès des Sc. Méd.*, tom. iii. p. 257., 2*d. sér.*) injected a watery solution of opium into the veins, in three successive cases of tetanus, with success. This practice was adopted in eight instances, and recovery took place in five. MM. DELPECH and DUBREUIL had recourse to the injection of a scruple of the watery extract of opium dissolved in two ounces of water into the veins of a lady, aged 50, attacked with tetanus consequent upon the application of a caustic to an ulcerated os uteri. This solution was injected after three intervals of about twenty minutes each. The patient fell asleep; the pulse became full, and 70 in a minute from being 120, and the muscles were relaxed. Upon wakening from her sleep, the tetanic contractions returned, about eight hours after the injection. The operation was repeated, and was followed by the same results. The patient, however, sunk on the third day. MM. PERCY and LAURENT further state, that they have injected twenty grains of the extract of stramonium, dissolved in half an ounce of water, into the veins of several persons attacked with tetanus, and with success. They have also injected a strong decoction of this plant with similar results; but the details of these cases are not furnished in the work in which this statement is made, nor is any notice taken of instances of failure. The injection of a solution of acetate of morphia into the veins of two horses affected with tetanus was tried at the Veterinary School at Alfort, but the result was unfavourable. Mr. SEWELL, of the Veterinary College, also tried this practice in a horse and in an ass, affected with idiopathic tetanus. The tetanic symptoms were removed, but the animals subsequently died from other causes, but not from a return of tetanus. (CURLING, *Opus cit.* p. 202.)

104. Other narcotics have received, comparatively, but slight attention in the treatment of tetanus. *Stramonium* was considered of service by Dr. BEGBIE (*Trans. of Med. and Chirurg. Soc. of Edin.*, v. i. p. 285.); and *Belladonna* was recommended chiefly as a prophylactic by M. SAUTER. The *Canabis Indica* was suggested, but I am not acquainted with any instances in which recovery from tetanus has resulted from its use: at least further experience of its effects in this disease is required.

105. *d. Alteratives* of various kinds have been tried for this malady, and several medicines, already noticed, have been prescribed in alterative doses, especially the bichloride and other preparations of *mercury*. When the disease is attended by morbid states of the blood, more especially by acid and other excrementitious materials accumulated in the circulation (§ 52.), large doses of the *fixed alkalies*, as advised by STÜTZ, or of *magnesia*, or of *ammonia*, as recommended by BLANKARD, after the bowels have been freely evacuated, will prove of service: but these should not be trusted to alone; they should be employed as will hereafter be recommended (§ 112.). The preference in such cases is due to magnesia, inasmuch as it both corrects this state of the blood and opens the bowels. FOWLER's solution of *arsenic* was prescribed by HULL, JENKINSON, HOLCOMBE, TAYLOR, and MILLER in large and frequently repeated doses, in conjunction with opium and stimulants. The last-named physician gave ten drops of this solution every hour with as much tincture of opium in a spoonful of brandy, in four cases of traumatic tetanus, which terminated favourably (*New Engl. Journ. of Med.*, &c., Boston, 1818.). The administration of alkalies internally in large doses with opium, and the employment, at the same time, of alkaline warm baths, although praised by STÜTZ, BEHRENDS, WILD, ELSE, and others, were denounced as inefficacious by MARCUS and FICKER.

106. *e. Antispasmodics* and *stimulants* have been very generally prescribed in the several forms of tetanus. Of these, the most frequently resorted to are *musk*, *camphor*, *assafœtida*, *amber*, *castor*, *spirits of turpentine*, *the æthers*, and *ammonia*, variously conjoined with each other, or with opium, alteratives, and other stimulants. AINSLIE, HUCK, ZANETTI, and others were favourable to the use of musk. CHESELDEN gave it with the tincture of opium, in moderate doses, and at short intervals. CHAPP and VOGT prescribed the same medicines, but in larger doses; and FOURNIER recommended the musk to be given with camphor. The following is nearly the same preparation as that prescribed by him: —

No. 347. ℞. Moschi, Camphoræ, sacchari albi, āā ʒj.; Tere cum Mucilag. Acaciæ ʒvj.; dein adde Spirit. Ammon. Arom. ʒij.; Infusi Arnicæ ℥v. Misce. Capiat Cochl. j. amplum singulis horis.

Assafœtida and *castor* were favourably noticed by Celsus, Aratæus, and Schultz, and many others; but, in modern times, they have been given in tetanus chiefly in conjunction with the other medicines just mentioned, or with opium, either by the mouth or in enemata. Fournier and Pescay consider *ammoniacum* one of the most certain remedies for tetanus, but that it should be given in frequent doses, carried as far as half an ounce in the twenty-four hours. A successful recourse to spirits of *turpentine* has been had by Phillips, Hutchinson, Peacock, and Gibbon, who prescribed this medicine by the mouth or in enemata. In either mode, as well as externally applied, it is generally of service (§§ 89, *et seq.*). The *balsam of Peru* has also been administered both internally and externally in tetanus. Dr. Kollock states, in Harless' Annals, that he gave as much as ʒij. of this balsam in the twenty-four hours, in a case which terminated favourably.

107. *f. Tonics* of various kinds, and conjoined with stimulants, or with alteratives, or with narcotics, have been frequently prescribed in tetanus, often, however, too indiscriminately, and without due reference to the form, state, or stage of the malady. Rush considered this disease as essentially one of debility, and therefore prescribed for it cinchona, ammonia, wine, brandy, cordials, &c.; but, in addition, he directed the wound to be early opened or enlarged, and to be filled with lint soaked in spirits of turpentine, in the traumatic form of the disease. *Tonics, stimulants,* and *aromatics* of various kinds, and in different combinations, had been recommended by Celsus, Aretæus, and others amongst the ancients; the most energetic in their operation was advised for tetanus by Harkness, Parkinson, and Bisset. Dr. Bright prescribed the sulphate of *Quina*, with other stimulants; Dr. Elliotson, the *carbonate of iron*, in large doses; Dr. Smith, the *sulphate of zinc;* Rush, Moseley, Plenk, and Fischer, the *cinchona* in powder, or in decoction. The free use of *wine* was advised by Hippocrates, Hillary, Rush, Currif, and Hosack I can only add that these, as well as antispasmodics, or stimulants, or alteratives, or narcotics are beneficial chiefly when prescribed with strict reference to existing pathological conditions. If the morbid irritability be characterised by debility, or by morbid states of the blood; if these states predominate over inferred inflammatory action in the membranes or substance of the spinal chord; if this action be not clearly indicated, or if it have been actively attacked by antiphlogistic measures; if the disease be traumatic or symptomatic; and if the secretions and excretions have been freely promoted and evacuated, then either of these classes of medicines, or various combinations of certain individual substances belonging to two or more of these, will be more likely to be efficacious than when otherwise employed. In these circumstances of the disease, tonics may be conjoined with antispasmodics, with alteratives, and with narcotics or sedatives, and be given every hour, or every two or three hours, according to their doses or to their effects. The following may illustrate such combinations:—

No. 348. ℞. Potassæ Hydriodatis ℈j.; Potassæ Bicarbon. ℈iv.; Tinct. Camphoræ Comp. ℥j.; Tinct. Cinchonæ Comp. ℥ss.; Tinct. Capsici ʒss.; Decocti Cinchonæ ℥vjss. Misce. Capiat Cochl. ij. larga, 2dis. vel 3tiis. horis, cum aquæ pauxillo.

No. 349. ℞. Moschi et Camphoræ, āā, ʒj.; Extr. Belladonnæ gr. vj. (vel Extr. Canabis Indicæ purif. gr. xii., vel Extr. Conii gr. xviij.). Tere cum Mucilag. Acaciæ ℥jss., et adde Ammoniæ Hydrochloratis ℈ij.; Hydrarg. Bichloridi gr. j.; Tinct. Serpentariæ ℥ss.; Tinct. Cinchonæ Comp. ℥j.; Decocti Cinchonæ (vel Infusi Valerianæ) ℥v. Misce. Capiatur Cochleare unum largum omni horâ, vel omni bihorio, in aquæ destillatæ pauxillo.

108. *g. Diuretics*, especially the *tincture of cantharides*, the spirits of *turpentine*, the spirits or oil of *juniper*, are said to have proved successful in cases of this disease by Gardiner, Brown, and Mease. The good effects of these are, however, most manifest when they have been given in such frequent or large doses as to irritate the urinary passages, or to occasion bloody urine. It has been said that the South Sea islanders, amongst whom traumatic tetanus is a frequent disease, endeavour to cure it by producing mechanical irritation of the urethra.

109. *D.* Successive and Combined Measures. —The *Treatment* of tetanus should not consist of an empirical employment of one or more medicines, the efficacy of which has been vaunted by some writers, doubted by others, and altogether denied by not a few. It is chiefly by a *succession* and *combination of means*, carefully considered and selected, and appropriately applied to the pathological conditions of each case, as far as these may be rationally inferred from the antecedents, and from existing phenomena. Much will necessarily depend upon the stage at which the case comes under treatment, upon the cause or causes which have produced the attack, upon the circumstances connected with the patient, and the means which have been already employed. The success of treatment will mainly also depend upon a right interpretation of the state of the pulse, especially between the exacerbations—upon the existing vascular action generally, and locally, as far as this may be inferred, from a close investigation of symptons, especially from the state of deglutition, from the seat and extent of the spasms, and from whatever appears to excite or to allay them.

110. In the treatment of tetanus and of several other diseases, certain misconceptions often mislead the inexperienced physician, not the least injurious of which are the following: — 1st, That bleeding will generally cure, and that it is necessary to the cure of inflammatory action:—2nd, That there are no other means than this, upon which any dependence can be placed capable of effecting this purpose:—3rd, That all tonics, antispasmodics, stimulants, narcotics, &c., are contraindicated, or are necessarily injurious, or at least inefficacious, where inflammation is present or blood-letting is required. It should therefore be recollected that, even when inflammation most unequivocally exists, blood-letting, when alone confided in, may be carried so far as to endanger life, without removing this state, especially when, owing to its seat, it occasions spasms or convulsions, or when its seat is the centre, or intimately connected with the centre, to which all impressions are conveyed and rendered objects of conscious sensation or perception, as is the case with the seat of tetanus and trismus. We ac-

cordingly find that blood-letting, when confided in alone, may be carried to the utmost, by repetition or otherwise, in the treatment of this disease, whether idiopathic or traumatic, and yet the desired result is not attained. Nevertheless, blood-letting, largely or repeatedly, may be required and prove most beneficial, when judiciously timed and directed, especially in the idiopathic form. But it generally requires several aids to the development of its efficacy, and, in tetanus more particularly, it is serviceable chiefly by favouring the operation of other means, although these means may seem calculated to produce effects very different from, or even opposite to, those expected from blood-letting. None of these means is more beneficial in this malady than purgatives such as have been mentioned above, aided, as occasion will suggest, by croton oil or other active cathartics, and by such other of the remedies noticed above as the circumstances of the case may warrant or require, especially by terebinthinates, internally and externally, by mercurials and by antimonials.

111. *a.* The *Symptomatic* or traumatic form of tetanus is not so manifestly benefited by vascular depletions as the idiopathic, unless the patient be young, robust, or plethoric; and unless pain be experienced in the occiput, cervical or dorsal regions of the spine; or other signs of the supervention of inflammatory action, upon irritation propagated to these regions of the nervous centres, be present; and in these circumstances blood-letting, general or local, or both, should be prescribed, according to the peculiarities of individual cases, and to the effects produced. Brisk cathartics, more particularly those already recommended, followed by antispasmodics, conjoined with sedatives or narcotics; or by tonics and stimulants, selected with judgment and prescribed with decision, are generally requisite, the period of exhibiting them, and the mode of combining them depending upon the acumen and experience of the physician. In this form of the malady, the *local* and *external means* mentioned above (§§ 80—89.) ought to be resorted to without the least delay; and be followed by active cathartics, and the other means which the progress and state of the disease will suggest. In this, as well as in the idiopathic, form of tetanus, *worms* often are present in the digestive canal, and either predispose to, or aggravate, the disease, more especially in warm climates, and in certain localities. Therefore the purgatives should have an anthelmintic operation, or *anthelmintic* medicines should precede the exhibition of cathartics, those already noticed being preferred, and administered by the mouth and in enemata.

112. In the symptomatic form of tetanus, where the indications of inflammatory action in the nervous centres or their membranes are hardly manifest, or are equivocal, — where violent spasmodic action and continued contraction are the chief and dominant symptoms, — the free evacuation of the bowels by chologogue, anthelmintic, and drastic purgatives, as already advised, ought to be the first *intention*, in connection with the local and external measures directed above. The next should be to support vital power and resistance, and to correct morbid states of the circulation, by administering the more powerful tonics, antispasmodics, and stimulants, in such combinations with each other, or with sedatives or narcotics, or with alkalies, as the circumstances of each case may suggest. If it be inferred, that the irritation has been excited, extended, or perpetuated by morbid or excrementitious materials in the blood, the free action of the excreting organs —of the bowels, kidneys, skin, &c.—should be promoted by the exhibition, either alone, or with tonics, stimulants, or aromatics, of diuretics, diaphoretics, and alteratives,—of alkalies, the nitrate or chlorate of potash, the citrate of magnesia, or precipitated sulphur with magnesia, camphor, turpentine, the balsams, &c.

113. *b.* The *sub-acute* states of tetanus require similar means to those already mentioned, prescribed appropriately to the features characterising individual cases. In these, as well as in the acute, the symptoms or signs of inflammatory action in the nervous centres or their membranes should be assiduously looked for; and if they be observed, the treatment ought to be directed accordingly. In this form of the malady, as well as in others, the most powerful agents are not always or even generally the most efficacious in arresting or controlling its course. Mild remedies, when appropriate in their operation to existing pathological conditions, especially when they are absorbed into the circulation and correct morbid states of the blood, or when conjoined with either of the several sedatives or narcotics noticed above (§§ 95, *et seq.*), are often more beneficial than the most heroic, more particularly in the milder forms of tetanus, in which it is often doubtful whether these latter are more injurious than serviceable.

114. It should always be recollected, that a judicious succession, as well as combination, of means is required for the cure of a disease which is so violent, so distressing, and so rapid in its course, as the acute forms of tetanus are; and we accordingly find in the histories of cases furnished by writers that such a succession and combination have proved the most successful. GILMORE had recourse to blood-letting, and administered calomel with camphor, soda, and brisk cathartics, followed by tonics and narcotics. WOODFORD prescribed blood-letting, calomel, Dover's powder, blisters, terebinthinate enemata, and the solution of tartarised antimony in frequent doses until it produced nausea, fœtid and black evacuations having been procured by means of the antimony and the turpentine injections, relief was then obtained. Several writers have observed the beneficial effects of large doses of the alkalies with opiates or other narcotics, after bleeding, purgatives, and other suitable means have been used. Dr. SMITH, after the operation of purgatives, applied from fifty to sixty leeches along the spine and behind the ears; and as soon as the leeches fell off, he kept constantly applied, over the whole length of the spine, cloths wet with a strong solution of the muriate of ammonia. At the same time he administered the wine of the seeds of colchicum, commencing with half a drachm, and increasing the dose every half hour or hour, until it produced vomiting, when it was no longer given. Other authors have shown that, after a due recourse to blood-letting and purgatives, in this malady, very different means of cure may be of service, in different cases, as blisters along the spine, followed by poultices moistened by an infusion of tobacco, wine and opium being taken at intervals; or the

cold affusion on the occiput and spine, followed by warm coverings, hot wine, spices, and opiates, the affusion being continued until approaching syncope, and these measures being repeated upon a return of the spasms; or the extract of opium conjoined with camphor and nitre, or with tartarised antimony; or the injection of a solution of a watery extract of opium into the blood, in addition to medicines otherwise administered; or the injection of a solution of tartarised antimony into the veins; or the administration, *per anum*, either of this solution, or of the infusion of tobacco, or of tobacco-smoke. A recourse to several of these more energetic means, more particularly the injection of powerful agents into the blood, and the administration of tobacco or tartarised antimony, always require the utmost caution. The effects of these should be carefully observed during a considerable time after they have been employed, in order to ascertain the propriety of repeating them, and that no time may be lost in having recourse to measures to counteract any injurious effects which may appear from them.

115. *E.* The Prevention of Tetanus or Trismus can rarely be entertained by the physician, as the circumstances indicating the contingent occurrence of the malady in its idiopathic form are seldom sufficiently marked, and still seldomer come under his cognisance. But it is a very important consideration to the surgeon. Much of what I have advanced when discussing the treatment of Shock (*see that art.* §§ 19—28.) applies to the prevention of this malady after severe injuries. But the chief means of prevention consist in promoting the excreting functions of the skin, bowels, and urinary organs, and in supporting the constitutional powers when these appear to languish, or are inordinately depressed by the shock, or by other causes. A dry and temperate state of the air, due ventilation, and the removal of the patient from unhealthy or miasmatous localities, or from crowded dwellings and narrow and insufficiently drained streets, are of the greatest importance in preventing the occurrence of the traumatic forms of tetanus.

116. *F.* Convalescence from tetanus or trismus requires much care as respects the regimen and medical management of the patient. The secreting and excreting functions ought to be duly regulated and promoted whenever they become torpid. The functions of the skin should be facilitated by occasional warm baths, by frictions, and by regulated exercise in an open and healthy atmosphere. The digestive organs always remain long weak and irritable, and require the use of mild tonics with soothing or sedative medicines, as the bitter infusions with hydrocyanic acid, &c., and a light diet. As the digestive functions become restored, the more energetic tonics, or chalybeate preparations, and mineral waters, may be given, and a more generous diet be allowed.

THERAPEUTICS, GENERAL PRINCIPLES OF—Physic, practical Principles of—Therapeia Generalis.

1. In the article Disease I have discussed — 1st. *The causation of disease, or Ætiology;* — 2nd. *The general doctrine of disease, or Pathogeny,—the several states of Morbid Action;* —3rd. *Diseases of the fluids, and more solid structures, generally originating in altered conditions of life,* especially in those previously discussed; — 4th. *The connection of Morbid Actions and of organic lesions with Morbid states of the Blood;* — 5th. *The Procession of Morbid Phenomena;* — 6th. *The Terminations of Disease;* — 7th. *The Relations, Alliances, Successions, and Complications of Disease;* — 8th. *The Mutations and Metastases of Disease;*—and 9th, and lastly, I have noticed, very briefly, *the Circumstances modifying the Form, Complications, Durations, and Terminations of Disease.* This article, in connection with those on the Blood, on Absorption (all written and published in 1831, 32, and 33), on Endemic and Epidemic Influences, on Infection, on Inflammation, and on Sympathy, constitutes a system of General Pathology, to which, although many years before the Profession, there is even now (1853) little of any importance to add, and in which I can find as little either to change or suppress. During this period, however, I have seen many of my ideas reproduced by others; and although I have been flattered even by this mode of adopting them, yet I have not had the honour of their paternity assigned to me. Of this I have reasonable cause to complain.

2. Having, under the above and other heads, considered the *Causes* and *Doctrines* of diseased actions, and the *Successions of Changes* following the predisposing, exciting, and accessary causes of disease, until either recovery or structural changes, and even death, ensue; and having, in the articles Auscultation and Symptomatology, and in others on the symptoms and signs of disease, discussed the phenomena and manifestations of general and special morbid action, it legitimately follows, that the *Principles* which should guide us in attempting the removal or alleviation of disease should be as fully developed and illustrated as the scope and limits of my work will permit.

3. In the articles on Endemic and Epidemic Influence, on Infection, on Protection from Pestilential and other Maladies, and in several other places, the most important and practical parts of Public and Private Hygiene have been fully treated of. Although the *prevention of disease* does not strictly fall within the scope of *therapeutical doctrine*, yet it is so closely allied to it as to warrant a reference to those places, where it is most appropriately considered,

in connection both with the causes which require prevention and counteraction, and with the effects which result when such precautions are not taken.

4. I. CIRCUMSTANCES RETARDING OUR ARRIVAL AT JUST PRINCIPLES IN THERAPEUTICS.—*A. Erroneous, limited, or one-sided views of the causes, seats, nature, and procession of disease — of medical doctrine* — are amongst the most influential means of retarding, and even of arresting, our progress in therapeutical knowledge, and in attaining to principles which may enable us to methodise that knowledge, and to advance its progress. The empirics and dogmatists of antiquity, the humoralists of much later times, the solidists and nervous pathologists of the last century, the doctrines of BROWN, the less philosophical and more limited views of BROUSSAIS, and other partial hypotheses, which never reached the dignity of being accounted theories, have set principles at defiance, and left reason out of consideration. Doctrines have been based on postulata; and what, in other hypotheses, may have been true of a species or variety, has been unjustly imputed to the genus or order. Inferences have been drawn from a few incorrectly observed facts; whilst assertions have been received as truths, and credulity has reposed upon them; worthless authority thus usurping the place of close observation and calm deduction.

5. B. *The neglect into which the vital endowment of the frame has fallen*, amongst modern pathologists, and the disposition to impute more to chemical and material changes than truly belongs to them, are also no mean causes of the retardation of the progress of sound therapeutical principles. The *vis vitæ*, the operations of Nature, constitutional power, vital resistance, &c., are terms which have been used synonymously with vital endowment; but whatever may be the name by which *vitality* should be recognised as a principle of our being,—as the chief essence or principle of existence, — it should always receive the first and chief consideration. Although partially or altogether neglected by many, and although results are imputed to other agents and causes which more especially belong to it, yet it on many occasions asserts its own rights, evinces its rule throughout its domain, and, whatever agents we may employ, and often even in opposition to injurious agents, it accomplishes those salutary purposes for which it is destined, and removes diseases which can be removed only by its influences. Whatever may be the object or intention with which medicines are administered, whatever the mode of prescribing them, the vital manifestations of the organ to which they are applied, or of the body generally, are more or less affected by them.

6. C. *Specious or novel plans or views, to which much greater importance is attached than they deserve* — Novelties, specious appliances, attempts at precision which cannot be reached, and various methods recommended by cunning persons to serve their peculiar purposes, and quickly caught up in order to serve the same ends, or to show extended information, severally tend to retard, and even to mislead, the march of therapeutical knowledge. The recent vaunting of the importance of medical statistics, and of numerical methods of proving the seat or nature of particular maladies, or the efficacy of particular remedies or plans of cure,— undue values put upon therapeutical agents, plans, or systems, —the vain parade of imported articles of medical belief, even although they may rank no higher than specious absurdities, are all impediments in the way of truth. A physician who has obtained by accident, by connection, or by talent of some kind, a position in his profession, asserts that a disease, or class of diseases, exists in certain numerical proportion, or presents numerically certain pathological changes or phenomena; and that the success of particular remedies or plans of cure may also be valued numerically as respects that or other diseases. The assertion, although so fallacious as to be almost absurd, yet being made by a physician of reputation or position, is believed, paraded as an astonishing novelty, and as an undisputed truth. Yet no hypothesis connected with medicine is more erroneous, inasmuch as there is not one disease which is always the same in all its features, in all places, or seasons, or times, or which is identical as to its precise seat, nature, or vital and material relations and associations. As there is not a single disease in the various and ever varying states of climate, of causes, of duration, of endemic or epidemic influences, of constitutional peculiarity, &c., that is identically the same, attempts at a numerical precision must necessarily be fraught with error, and be productive of most injurious results; the specious appearance of a precision which the nature of the subjects to which it relates cannot reach, or even approach, misleading those who prefer authority to deep thought, and a striking novelty to close observation.* This is only one of the several specious plans

---

* There cannot be a more absurd belief than that confided in by some recent writers, who have adopted the numerical method, not only of describing the causes and symptoms of any particular disease, but also of treating such disease. Thus our Continental brethren, and our domestic imitators, having assumed that the disease is pneumonia, or pleuritis, or peritonitis, or any other specific form, without noting the influences of climate, season, age, constitution, endemic or epidemic conditions, duration, complications, &c., are not content with informing us that so many in the hundred presented a certain symptom, or proceeded from a particular cause, and that another number in this hundred furnished different results, but they go even further, and, endeavouring to enlighten us still more, tell us that a certain number per cent. of a certain disease was cured by one medicine, another certain number was cured by another medicine, the one which cured the most being *the* remedy for that disease; as thus most irrefragably proved by this most admirable statistical or numerical therapeutical method! Let me take a recent illustration of this most admirable method, as furnished by a most distinguished medical *savant*, somewhere between this and the Black Sea. He takes a large number of cases of a disease which he has assumed to be, or is pleased to call, *pneumonia*, but of the truth of which we have no evidence, and none whatever of the causes, of the characters, of the duration, of the morbid associations or complications, &c.—no proof whatever whether or not they were cases of sthenic, or of asthenic or congestive pneumonia, or of broncho-pneumonia, or of peripneumonia. He represents these numerous cases as pneumonia, although it is well known that pneumonia presents very different and even opposite features, and conformably with such features requires very different and even opposite means of cure, —means varied and appropriate to each case and to each state and stage of the malady. But the enlightened and illustrious therapeutist makes short work of his numerous cases. True to his faith in numbers—to his infallible "numerical method," he divides his devoted, although numerous cases into three equal parts. These three equal numbers — these three forlorn hopes, which thus are led to storm the stronghold of scientific and rational medical practice—are each very differently treated: one devoted third is treated by blood-letting alone; an-

or novelties which the love of notoriety, or the desire of distinction, has thrown out to the credulity of the multitude, each one having its own crowd of believers, until another supersedes its supremacy for a time,—until it, in its turn, sinks under the influence of a successor, the revolving wheel of time at last turning up anew the theories, the plans, and the beliefs of past ages.

7. D. *Wrong estimates of the efficacy of particular medicines and agents* are as influential in retarding the progress of therapeutical principles, as the adoption of erroneous doctrines of the causes, seats, or nature of disease. Therapeutics is based equally on sound pathological principles, and on a knowledge of the operation and efficacy of medicine—of the instruments which we employ for the removal of morbid conditions. It requires not the lapse of many years to show the experienced physician the perishable reputation of many of the agents which have been employed against disease. Worthless agents have often been adopted; means which possess little influence have been over-estimated; and others which are efficacious when judiciously used have sunk below their true value, or even fallen into disuse. Fashion, undue estimates, improper and irrational employment, have contributed their respective shares in retarding our knowledge of therapeutical agents, and in preventing us from accomplishing therapeutical intentions. The same revolutions which have taken place in respect of medical doctrines during many centuries have likewise taken place as to therapeutical agents; the vanity of some, the cupidity of others, and the sanguine or enthusiastic views of a few, leading those into error who trust to authority, and who are deprived of the means or the powers of original research and profound observation.

8. E. *The licence allowed by the laws to charlatans, impostors, and systems of imposture,* and the credit which these obtain with the public, owing to the confidence of their assertions and the false testimonies they produce in support of their delusions, are injurious to the progress and reputation of scientific medical practice. The cure of disease being essentially a most important and high profession, all who pretend to it receive from the public an amount of notice great in proportion to the parade, rather than to the justice, of their pretensions. Hence the high standard of medical profession is lowered; and every pretender, whilst he detracts from this standard, derives to himself a reputation with the credulous public which is altogether opposite to his deserts. These impostors, by assuming characters which do not belong to them, and which the negligence of the legislature, and the worse than negligence of the expositors of a most imperfect legislation, not only permit, but even encourage, by thereby lowering the prestige of medical science, and by diminishing the amount of encouragement held out to learning and science, actually retard the progress of scientific research, of professional learning and observation, and consequently of practical medicine.

9. F. *But the most remarkable cause of the slow progress of therapeutical science is to be found, in the highest and most legitimate ranks of the medical profession—in physicians themselves.*—Public institutions for the cure of disease, in very few instances in this country, and, even these only in recent times, have furnished the amount of knowledge to the profession which they are calculated to furnish; and many of those, who have been engaged for the greater part of their lives in treating the diseases received into the wards of these hospitals, have gone to their graves either without having thrown any light upon the obscurities of pathology and of therapeutics, or, if any such light had broken in upon the darkness of their mental vision, it had never been reflected to others, or enlivened the gloom in which they had shrouded their ignorance. Other physicians have enjoyed the patronage not only of the public but also of their profession, and must have had their minds stored,—if, indeed, capable of obtaining and retaining such stores,—with pathological and therapeutical knowledge, and have sunk into the tomb without furnishing a single fact, precept, or opinion, by which their names could be rescued a single day from their deserved oblivion. Thus the springs of therapeutical science have either been dried at their very sources, or have been absorbed by the barren and sandy soils through which they had most unfortunately passed. Others, with a more determined selfishness, reserve to themselves, and to their own uses, and for their prospective gains, the results of the experience they may have reached, and of the researches they may have made; and, without reflecting that the attainment of knowledge imposes the duty of imparting that knowledge to others, as a grateful return for the kind Providence of attaining it, do all in their power to turn it to their own advantage, and to prevent it from coming before the profession or the public. This last cause, however, of the retardation of therapeutical knowledge is much less remarkable than formerly, and is rarely to be observed at the present day.

10. G. *The want of correct ideas as to the physiological action of remedies* is one of the most powerful causes of the retardation of therapeutical knowledge. It is obvious that, even when the causes and nature of a disease are clearly indicated and recognised, if the physiological action,—the *modus operandi,* of the agents prescribed be not accurately known, the indications of cure cannot be successfully fulfilled, unless, indeed, the vital resistance of the frame be such as overcomes the injurious or wrong-directed means. Hence the propriety, as will be shown in the sequel, of ascertaining with precision the true action of the means employed—of using aright the instruments of cure.

---

other devoted third, by tartar emetic only; and a somewhat more fortunate third is left entirely to the unaided efforts of Nature. Can there be any doubt of the result, when we know well that many cases of pneumonia, instead of blood-letting, or tartar emetic, in which cases these means are certain destruction, require camphor, ammonia, and other remedies very different from those he has experimented on? What this empyrical admirer of the "numerical method" inferred, when he found that Nature was the best doctor, may not be manifest. But she is undoubtedly very greatly to be preferred to the *soi-disant* physician, who treats disease according to the name he chooses, often irrationally, to give it; and without adapting or combining his agents in such modes as an enlightened physician would employ and direct them to the removal, the counteraction, or to the relief, of such existing morbid actions as pathological science would enable him to detect and estimate with due accuracy.

11. *H. The prejudices, also, of those who are submitted to medical treatment, and the neglect of others,* although chiefly preventing the success of treatment, likewise retard the advance of this department of medical science. Many persons submit to treatment to satisfy their friends, without belief in its efficacy, or at least with a conviction that medical care cannot avert their fates, or change the decrees of Providence, not knowing, or not believing, that the means are required to be used by us before the blessing of the Almighty can be accorded to them; and that those are most certainly aided by Divine power who use every endeavour to aid themselves, whilst those who mistrust their own, and other human efforts, most frequently reap the fruits of distrust and unbelief. The neglect of patients themselves, although confiding more or less in medicine, to follow out with care the injunctions of the physician as to its use, and as to diet, air, exercise, and regimen, often mislead him as to the operation and the success of the means which he has prescribed, and induces him to attribute either too little or too much to their influence.

12. *I. Medical jealousies and contentions; opposing systems, plans, or means of cure; jarring views as to the efficacy or operation of certain medicines; opposite opinions in courts of justice, or otherwise appearing in public; the publicity given to medical discussions,* especially when different views are warmly espoused, have severally and collectively an unfavourable influence on the public, especially at the present day, and prevent many from trusting to medical treatment, at least for such a period as is requisite for their cure. These circumstances induce many to have recourse to charlatans, whose confidence and assurances impart a similar sentiment in them. The impatience, also, of those who ought to be patient; the frequent changes of their medical advisers, and the consequent discordance of their views and of their means of cure; the recourse to new plans or agents before those previously employed had received due trial, or their effects observed, together with various other circumstances depending upon both physician and patient, and with the too frequent incongruity of the means prescribed, not merely retard or prevent the recovery of the patient, but also exert a similar influence on the progress of therapeutical science.

13. II. THE PRINCIPLES OF THERAPEUTICS. — My limits prevent me from noting the earliest attempts to develope the principles of therapeutics, or the more recent efforts at a satisfactory arrangement of these principles. The reader who is desirous of satisfying himself as to these matters, may do so by referring to the works enumerated in the BIBLIOGRAPHY. Without adopting, or in any way following, the methods of others, I shall draw upon my own resources, and state what extensive observation and prolonged experience have induced me to believe. Although on this, as on many other occasions, I furnish the references for those who choose to have recourse to them, yet the opinions or doctrines which may be there found, and those which will be here enunciated, if they agree at all, or in as far as they agree, may be viewed as accidents or coincidences, and as evidences of their truth, rather than that I have been indebted for them to any of the sources there indicated.

14. i. FUNDAMENTAL PRINCIPLES OF THERAPEUTICS — THE ESSENTIAL BASIS OF THERAPEUTICS.—*A. To endeavour to interpret aright the operations of Nature, and not to interfere with them when their procession is conducive to the removal of morbid states, or to a return to health, but to aid and to develope them when aid is required.* — This precept is evident to all observing and experienced minds; but it is not always adopted by the inexperienced. When a person is seized with epistaxis, or with vomiting, or with diarrhœa, or with a hæmorrhoidal discharge, inexperience may attempt to arrest it, and thus to change a salutary evacuation to a dangerous malady. If these were duly watched, the effects carefully observed, and allowed to proceed, either until they subsided spontaneously, or until it became obviously requisite to arrest them, cerebral congestions and determinations, hepatic obstructions or congestions, or other serious affections, which often follow upon their premature arrest, might be averted. It not infrequently occurs, that either of these discharges, especially when scanty, or insufficient to produce a salutary effect, points the path which should be taken. Where Nature directs, we should follow; and, although her steps may not be exactly those in which we should always tread, the principles she inculcates ought to be adopted, and carried as far as an enlightened experience, or a reasoning observation, will warrant.

15. *B. We should next endeavour to ascertain the causes, the mode of accession, the duration, and the extrinsic and intrinsic circumstances influencing the progress, of the disease.* — *a.* It is obvious that the nature of the *cause* will always most materially influence the state, course, and termination of the malady. The cause often becomes identified with, and forms, as it were, a portion of the constitution of the disease. A poisonous seminium, emanated from an infected person, impregnates the frame of another, imparts a specific character to the resulting malady, in all its successive and spreading disseminations. Malaria invades the frame, and produces effects commensurate with the concentration or dose of the poison and the susceptibility of the individual. The inflammations resulting from the more usual causes of suppressed perspiration, or of interrupted eliminating processes, manifest different features from those which result from special animal emanations, or other poisons: whilst the former are more or less sthenic or limited, the latter are spreading, erysipelatous, contaminating, or infectious. (See *Arts.* ENDEMIC and EPIDEMIC INFLUENCES, ERYSIPELAS, INFECTION, POISONS, &c.)

16. *b. The mode of accession* is often an index to the future character and course of the malady. If the accession is clearly connected with the cause, and such as the cause usually produces, both the nature and the treatment of the disease are often clearly indicated. Thus, if a person experiences chills or rigors, but complains of no remarkable pain or other affection of an organ lodged in any of the cavities, although there be pains in the head, back, and limbs, and if he can trace his disease to exposure to any of the usual sources of malaria, either intermittent or remittent fever may be considered as having commenced; and if, after such rigors and such exposure, heat

of skin, vascular reaction, and the other usual symptoms of febrile excitement be present, the nature of the malady becomes still more manifest, although a further time, probably only a very few hours, may be required to demonstrate the type of the malady. In such cases, an emetic, followed by a chologogue purgative, and by free evacuations, and these, at the due period, by a powerful dose or doses of quina or of cinchona, &c., will make a salutary impression on the frame, will break the chain of morbid actions, and prevent the succession of febrile paroxysms. This connection of the cause with the accession of the disease it produces, is still more remarkable in respect of specific and infectious maladies, and often not less so as regards endemic and epidemic diseases, and often furnishes a sufficient basis for therapeutical intentions.

17. *c. The duration of the disease*, when the physician is first called, and the previous history of the case, obtained with all possible precision, are essential to a proper treatment of it. The stage at which it has arrived; the existing pathological conditions, as far as they may be traced; the probable degree of vital power or resistance; the evidence as to the state of the blood and of the depurating organs and functions; and the means which have been already employed, and the effects produced by them, should be severally estimated with all the accuracy in our power. It is obvious that, as disease is generally a succession of morbid actions, leading either to the restoration of health, or to exhaustion of vital power and deterioration of the fluids and structures, so should the progress in either direction be carefully considered, and the indications and means of cure directed accordingly.

18. *d. There are numerous intrinsic and extrinsic circumstances influencing the character and tendency of a disease* which ought to be duly considered by the physician, inasmuch as a recognition of these, and a careful estimate of them very often, should direct or modify both the indications and means to be adopted. I can merely enumerate these circumstances at this place, as a more full consideration has been given them under different heads. The several *epochs of life*, from infancy to extreme old age, not merely have diseases which are especially incidental to them, but also very remarkably modify the features and tendencies of those which are common to all ages. (See *Art.* Age.) — The *temperament* and *habit of body*, particularly as respects vascular fulness and inanition, or anæmia, are of great importance, as I have shown in the article Blood (§§ 13—77.). *Varieties of the human species* and *differences of race* very remarkably influence not only the predisposition to, but also the treatment of, many diseases, especially those of a febrile, inflammatory, and epidemic nature; and when individuals of any variety or race have migrated from a climate in which they were indigenous, to one more or less different in the several physical elements and circumstances which constitute *climate*. The pathology and treatment of diseases, with reference to difference of race or variety, was for the first time duly considered in this work. The *occupation* of the individual not only induces many diseases, but also modifies others. (See Arts and Employments, &c.).—The *habits* and *mode of living* usually adopted by the patient both modify the character of many of the diseases to which he is liable, and require modified indications, means of cure, and regimen. They are even productive of several others, as fully shown in the article on Disease (§§ 18, *et seq.*). In addition to these, certain Diatheses and hereditary diseases should not be overlooked, and, of the former, the Scrofulous, the Gouty, and the Rheumatic, are the most important.

19. *Mental impressions, emotions*, &c. have a powerful influence in modifying, as well as in predisposing to, disease; and this influence is very generally exerted during the whole course of the malady, favouring, and sometimes even occasioning, an unfavourable or a favourable issue, according to the nature of such impressions or emotions. These affections of mind ought always to be duly considered by the physician before he forms his indications or selects his means of cure. In severe, dangerous, and infectious maladies, the patient often entertains anticipations of the result, which occasion their own fulfilment. When these anticipations are unfavourable, and especially when they amount to convictions in the patient's mind, then they should be combated not only morally but physically. They should even direct the indications and the means of cure, the most powerful remedies being then required to rouse the vital powers and resistance, to arrest exhausting discharges when these are present, and to restore the depressed energy of the organic and cerebro-spinal nervous systems. Several slighter and more chronic maladies either are rendered more severe, or are prolonged, by mental disquietude or anxiety, — by some cause depressing or irritating the sentiments, emotions, and passions. The mental condition and circumstances of a patient should, therefore, be ascertained, when the state of disorder indicates any disturbance in this direction, and ought to be directed accordingly.

20. *Several extrinsic influences* modify the character, nature, type, and terminations of disease, not merely in as far as they are the occasion of it, but chiefly by the impression they make on the frame during the course of the malady. *Climate* remarkably affects the prevalence and nature of many diseases; and requires that the indications and the means of cure should be directed and modified accordingly—and with reference not merely to those persons who are indigenous and acclimated, but also to those who have recently undergone a change of Climate. (*See that Article.*) Endemic and Epidemic Influences (*see these heads*), confinement in an infected atmosphere, or in crowded or ill ventilated apartments and localities, emanations from burying-grounds, sewers, drains, cess-pools, or water-closets, and the numerous sources of atmospheric contamination described when treating of the causes of Pestilence and of the means of preventing it, severally not only produce disease, but aggravate its character when the patient continues to be subjected, during its progress, to any of these causes.

21. *States of weather* and *season* have also great influence upon the course of diseases, certain ranges of temperature favouring the occurrence of some diseases, or even being necessary to the diffusion or to the infection of others; especially of infectious, pestilential, and epidemic maladies. The influence of season, weather, winds, and, more es-

pecially, of ranges of temperature, not merely on the diffusion of disease, but also upon its general character, is so well known that it is unnecessary to furnish any illustrations of the fact at this place, as they are fully adduced, under their respective heads, when treating of the maladies chiefly influenced by these causes, and in the articles Disease, Infection, &c., and in those just referred to.

22. Amongst other influencing extrinsic causes, the *prevailing epidemic constitutions*, as well as those just mentioned, and generally in connection with them, require strict attention when forming the indications, or selecting means of cure. These epidemic constitutions often continue many years, and the prevailing diseases present either a high range of sthenic diathesis, or a general asthenia, or depression of vital resistance to the progress of morbid changes. In the former, the character of diseased actions is sthenic, inflammatory, and recuperative; in the latter, it is adynamic or deficient in vital power. The sources of these prevailing constitutions have not been satisfactorily shown. They have been imputed to a prevailing character of the seasons, to the annual amount of rain fallen during a series of years, and to the states of terrestrial and atmospheric electricity—to either or all of which they may be referred, although the proofs respecting them are not quite conclusive; and are not sufficient to exclude the influence of other, or even of unknown agencies.

23. C. *To determine the pathogeny of disease—to ascertain existing pathological conditions, and the morbid tendencies characterising them*, is the chief basis on which indications of cure should be founded. This is the great *axiom* in rational therapeutics, and, unless due regard be paid to it, medical treatment is worse than empyrical:—it is often destructive of life,—it entirely subverts its own intentions. This being the case, the utmost care should be taken to arrive at accuracy respecting these conditions, and as to their several tendencies and consequences if they be not arrested or controlled. Due consideration ought likewise to be given to those topics which have been already discussed. The existing pathological states having been rationally inferred from every fact and circumstance connected with the disease, and from its causes and modifying or accessary influences, the indications and means of cure should be appropriately directed to remove, or to control, or counteract them, according to their natures and tendencies, as shown in the more *special principles of therapeutics* (§§ 36, *et seq.*), and fully illustrated in the consideration of the specific forms of disease, under their several heads.

24. D. *To remove all predisposing, exciting, and concurring or accessary causes, as far as may be in our power*, is obviously necessary to the removal of the effects resulting from these causes. The causes of disease, especially those which are exciting or most influential, are often so obvious, and their connections with their effects are so demonstrative, that the existence of the former leads us to infer the latter; and a due manifestation of the latter is indicative of the former. This is especially the case in respect of specific, infectious, contagious, febrile, endemic, and epidemic maladies. But there are other diseases which are the effects not of one or even of two causes merely, but of several. There are numerous circumstances which influence, by predisposing or by counteracting, the susceptibility of the individual to the invasion of the exciting or efficient causes of disease; whilst there are many more which concur or reinforce these causes, either at the time of, or subsequently to, their morbid impression and action. Some of these may escape detection or due estimation, whilst others may have an undue importance assigned to them. Still it should be our strenuous endeavours to ascertain their existence and influence with due precision, in order that they may be removed orcounteracted.

25. ii. General Therapeutical Principles and Precepts.—*A. Of indications and contra-indications in the treatment of disease.*—Indications or intentions of treatment or cure are those objects or ends which we propose to attain, in order to remove altogether, or to alleviate disease when removal is no longer attainable, owing to its nature or progress. Contra-indications are such intentions or means which would, reasoning from existing phenomena and pathological states, either not remove or benefit these states, or would aggravate them, and thereby risk the life of the patient. Indications of cure are to be accomplished or fulfilled appropriately and successively, by a careful and accurate deduction from existing morbid conditions and tendencies, and with a strict reference to the fundamental principles noticed above, to facts, and to the considerations and reasonings which accurately observed facts suggest. Having observed with care and acumen, and drawn rational indications from a close and comprehensive view of both the intrinsic and extrinsic circumstances of the case, the next object is—

26. B. *To employ agents or means,—remedies or medicines,—for the fulfilment of those indications or intentions that are the best calculated to this end.*—But to attain an object, to accomplish an intention, it is most requisite to entertain accurate views as to the mode of action, the proper methods of employing, and the efficiency of, the agents, instruments, or means which we may recommend. The physiological action of medicines, in different doses or quantities, ought to be known, and the operation of the same medicines and doses be ascertained, in different diseases, by a careful experience and close observation. Having previously known the modes in which agents or means become remedial or instrumental against disease, those agents or medicines should be employed with strict reference to the removal of existing morbid states, as far as they may be ascertained, and with the intention of preventing progressive disorder, a strict regard being always had to the physiological and pathological operations of these medicines or agents.

27. C. *To closely observe the states of vital power and resistance, and the grades and character of vascular action, in connection with the condition of the circulating fluids and of the several secreting and excreting functions.*—Our means should always have regard to the vital manifestations, recollecting that agents become remedies only when acting on vital states, and appropriately to a correct interpretation of these states,—when they calm or lower vital excitement, or morbidly increased vascular action, if either of, or both these pathological conditions are present, and when they

restore vital power or impaired vascular action, if either of, or both these states require restoration. But it is not only necessary to attend to the grades and character of vital power and of vascular action and reaction; the conditions of the circulating fluids, and of the secreting and excreting organs, should be ascertained with all possible accuracy. The condition of the circulating fluids, especially of the blood, can often be inferred only from the activity, from the torpor, or from the suppression of one or more, of the eliminating or depurating functions, and from the appearances of the skin, extremities, and the outlets of mucous canals; it may be further inferred, on many occasions, from the states of the heart's action, and of the pulse, in connection sometimes with the appearances and the changes of the blood itself, when taken from a vein. Whatever may be the changes, the signs, or the phenomena which may guide our inferences as to vital power, or to vascular action, or as to normal or anormal conditions of the fluids or solids, these inferences having been rationally drawn, the indications of cure conclusively follow, and are to be fulfilled by medicines selected conformably with their known operations.

28. *D. To take into consideration not merely the states of vital power, of vascular action, and of the excreting and depurating functions, but also the diathesis, the general aspect, the complexion, the posture, the nutrition, and the physical power of the patient.*—In addition to these, the circumstances in which the patient is placed, and by which he is influenced, whether mental or physical, — whether intrinsic or extrinsic, — should be duly estimated conformably with the influence they may severally or collectively exert in favouring, or in counteracting, the indications and the means of cure; and these means should be selected with due reference both to these indications, and to these moral and physical circumstances which are never present without influencing, more or less, the present condition, and the course and the terminations of the disease; and, moreover, without modifying the effects of remedies.

29. *E. To select the means of cure with strict reference to what is known of their modes of action, and, conformably with this knowledge, to employ them appropriately to inferred pathological conditions.*—Medical agents are remedial only as they are rationally or appropriately prescribed. In order that they may be so employed, it is requisite to bear in mind the following propositions:—1st. That medicines should be given in forms which may best produce their desired effects; — 2nd. That the vehicles in which they are given, should also possess this property;—3rd. That the substances with which they are associated, ought to be such as either will develope their effects, or will concur in producing the same effects;—4th. That substances which act upon more than one function, surface, or viscus, ought to be cautiously prescribed, and with especial reference to the function or viscus on which their operations are desired; — 5th. That when medicines are likely to occasion nausea, pain, or distress, these effects should be avoided by combining them with substances which may prevent or correct such discomforts; — 6th. That, when it is desired to influence more than one organ or system, agents whose actions have been shown to be thus complex, may then be selected with these intentions, or several may be conjoined with these views, provided that they are chemically compatible, suitable to the ends proposed, and altogether congruous with each other; — 7th. That the combination of medicine producing different effects, often occasions additional effects, different from those produced by either, and frequently without materially disturbing the action proper to each. These propositions, although almost self-evident, require a few remarks for their elucidation. My limits, however, require that these remarks should be very brief.

30. *a.* The form best suited for the production of the effects of a remedy, is that which conveys either all, or the greatest amount, of the properties characterising the remedy, and which presents these properties in the most suitable state for their immediate, or for their more protracted operation, as either may be required. Thus the more immediate and full operation of medicines is most frequently obtained by infusion or decoction, by dilution, or in the state of tincture or essence, according to the nature of the substance; or by trituration or minute division, if the substance be more or less solid. In the states of solid, and extract, or in the form of pill, many substances either may long remain in the stomach without being acted upon, or may pass the pylorus, and either occasion a very delayed or a very imperfect effect; and when pills are gilded or silvered, their operation may be still longer delayed, or they may pass off without being dissolved. When the operation of medicines upon the lower bowels or uterus is desired, then the form of substance, extract or pill, may be preferred.

31. *b.* The vehicles best suited for the administration of active medicines, should be congruous with the operation of these medicines, and such as may prevent the stomach from being disturbed by them, and at the same time promote their operation. Thus the action of the disulphate of quina is promoted by taking it in the compound infusion of roses; the tinctures of cinchona, in the infusion or decoction, or in an aromatic water; the several tonic tinctures, in bitter and aromatic infusions; and the purgative tinctures or salts, in laxative or purgative infusions; neutral salts, in states of much dilution; powders, in aromatic infusions or waters; and the active ingredients for enemata, in vehicles which will admit of their administration in due or equal admixture.

32. *c.* That several substances whose effects are congruous, or calculated to develope their mutual actions, are often most beneficially prescribed together, cannot be controverted, especially in cases requiring a decided operation on the secreting and excreting organs, and a due development of the several vital manifestations. Thus various purgative or cathartic substances are combined with advantage; several stimulants, with antispasmodics; tonics, with stimulants and aromatics, &c. Quina, or the disulphate of quina, is advantageously given with camphor, in many cases requiring the former; or cinchona with ammonia, or with serpentaria, or with both; or myrrh with assafœtida, galbanum, or ammoniacum; or infusion of vale-

rian, with tincture of sumbul, or with ammonia, or the æthers; the preparations of iron, with those of quina, or with those of calumba or quassia; the preparations of scoparium, with those of taraxacum, juniper, &c., or these with the salts of potash, &c., or with diuretic spirits or tinctures, &c.

33. *d.* It is often desirable to have recourse to substances which affect more than one function, or to combine medicines which affect different organs, due regard being had to the function requiring to be chiefly acted on. Certain medicines, particularly those which are alterative, and more or less specific in their operations, produce, according to their doses, the frequency of their repetition, and the nature of the disease, changes in more than one organ or function. Mercurials, antimonials, iodine, and the iodides, sulphur, magnesia, and the alkalies, &c. may be adduced in illustration of this position. Whilst sulphur acts on the bowels, it is partially absorbed into the blood, and acts also upon the skin, increasing both the cutaneous exhalation and the follicular secretions. Magnesia opens the bowels, is partially absorbed, and neutralizes and counteracts excrementitial materials in the circulation. Alkalies and the iodides combined with alkalies, affect the blood, and through it the several emunctories and solids. Camphor passes into the circulation, affects the nervous system, and promotes exhalation from the lungs and expectoration; the terebinthinates also are absorbed, and act upon the capillary circulation and on the kidneys, &c. Many of the neutral salts act upon the bowels; and being absorbed, especially when taken in doses which are not purgative, excite the kidneys to increased action, and sometimes also the skin, &c.

34. *e.* The action of medicines may cause discomfort or painful symptoms, which should be prevented or counteracted by adding substances which will correct these unpleasant effects. Purgatives, especially those which are cold, saline, or nauseous, and substances which in large doses occasion vomiting, frequently are rendered both more pleasant and more active, by conjoining them with aromatics, or with spices, or with bitters, or with both, and sometimes also with anodynes or narcotics; or by giving them in finer divisions, or in more diluted states, either similarly combined, or in smaller and more divided doses.

35. *f.* Medicines possessed of different properties may be conjoined, when it is desirable to affect more than one function, organ, or system; provided that the action of the one substance does not counteract that of the other, and that they are chemically and vitally compatible with each other. Thus the alkalies, the combination of them with boracic acid, or common borax, the nitrate of potash, magnesia, and the citrate of magnesia, severally change the states of the blood, especially when uric acid or the urates and fibrin are in excess in the blood, or when this fluid is loaded with excrementitial materials. They neutralise these materials, and promote their removal by means of the emunctories; and, when they are conjoined with tonics, or with febrifuges, or with bitter infusions, they promote the salutary effects of those, especially in periodic and low fevers, more particularly when they are given in the decoction of cinchona with serpentaria, or with camphor, arnica, &c. Those deobstruent and alterative substances, or the iodide of potassium, with the solution or the carbonate of potash, and with the tonics now mentioned, are also most beneficial in several states of rheumatism and gout, in some diseases caused by malaria, and in several other maladies, chiefly owing to the combination of means and to their conjoint actions.

36. *g.* The combination of medicines possessed of different properties, often gives rise to different or to additional effects, those characterising each either still appearing, or being masked by the effects resulting from the combination. Sometimes the effects are a combination of those produced by each ingredient, as when tonics are combined with aperients or purgatives. The true DOVER's powder, or the association of ipecacuanha and opium with the nitrate of potash, produces an effect beyond those which characterize these constituents; yet their individual properties are more or less manifested. Disulphate of quina, conjoined with one-tenth of the quantity of aloes which is usually required to open the bowels gently, produces a cathartic operation. Small doses of opium tend to determine the action of medicines, which are apt to disorder the stomach or bowels, to the skin or to the kidneys, as when they are conjoined with antimonials, or with ipecacuanha, or with colchicum, or with the common diuretics.

37. III. SPECIAL THERAPEUTICAL PRINCIPLES —The special consideration of therapeutical principles has been partly discussed under other heads; but it may not be without advantage to bring the whole subject, in a full and connected manner, before the reader, referring him to those places in which certain topics are as fully considered and illustrated as the scope and limits of this work will permit, in order that repetitions may be prevented both in this and in other places.

38. i. THE RESTORATION OF NERVOUS AND VITAL POWER, WHEN PRIMARILY DEPRESSED, is very often necessary; and the physician is called upon to accomplish this intention in a great variety of circumstances,—in cases of mental and physical SHOCK (see that Article); after the impression or action of numerous sedative, poisonous, or noxious causes; upon the invasion of any of the several infectious and pestilential maladies; in the cold stage of periodic fevers; and in the several forms of local or general DEBILITY (§ 5, *et pluries*). In these, and even in other circumstances of disease, either the organic nervous energy, or the vital power generally is more or less depressed; but this may not be the only morbid condition. It may be associated with others in various grades, equally requiring attention and removal; but when it constitutes the prominent or chief affection, the others may arise from and depend on it, and the vital depression then imperatively requires removal. When the depression is a primary effect of known, specific, or poisonous causes, the continuance of it may then be followed by one or other of three results:—1st. It may become more and more urgent, or may increase until the vital manifestations entirely cease; —2nd. It may be followed by imperfect or abortive efforts at reaction, life at last sinking in the struggle;—3rd. When the vital energies are not subdued in either of these modes, reaction of a

tumultuous or excessive kind may supervene, and endanger the integrity of the structures or organs most predisposed to organic alteration. These results are the more likely to occur, when specific, infectious, or poisonous causes occasion the primary vital depression; inasmuch as the functions of the secreting and excreting organs are then early impaired or interrupted, or entirely suppressed, and the blood and other circulating fluids are more or less altered, contaminated, or poisoned. In this, as well as in other states of disease, the Indications are:—1st. *To ascertain and to prevent the further action of the causes occasioning vital depression*;—2nd. *To remove the effects already produced*;—and 3rd. *To prevent or counteract contingent or consecutive results.*

39. *A.* The *first* of these, although not always possible, may often be accomplished. A contaminating air may be corrected by ventilation, or by removing either the sources of contamination or the patient from their influence. But a specific infection or contagion, having once made its morbid impression, cannot be prevented from producing the succession of changes which characterise its effects, although these changes may be aggravated and vital power depressed by a humid, impure, or contaminated atmosphere; the second and third intentions are, therefore, to be attempted. Malaria, in any of its states, may have made its impression on the frame; and, although removed, the effects will take place in the form of vital depression, chills, rigors, &c., followed by vascular reaction, perspiration, &c. But if the patient were to remain during the progress of the disease, subjected to the continued influence of this cause, the disease would be more severe, more difficult to remove, and more prone to occasion structural changes in predisposed organs, and might even assume a more continued and dangerous type. There are numerous external or physical agents which depress the organic nervous energy, and through this system lower the vital manifestations; and there are many mental, and intrinsic, and even structural conditions which produce similar effects, without being clearly evinced or ascertained. In these circumstances, although the causes, and the changes which they have induced, may be loosely inferred; yet their removal or prevention may not be within our power, and the next indication is to be at once attempted.

40. *B. Secondly*, To remove the depression already produced, is an intention which should be fulfilled by means, as respects their powers and natures, appropriate to the grade of depression and the phenomena characterising it. But these means should have more or less reference, not only to the state of depression, but also to its causes — whether mental, physical, specific, infectious, &c. They ought to be sufficient for the end proposed; but not excessive in their operation, or such as are likely to occasion inordinate excitement or reaction, or irritation, or inflammation of the organs to which they are directed. In the more extreme cases, or when vital power is remarkably depressed by the invasion of infectious maladies, the more powerful stimulants are then required, aided by external measures, in order to determine the flow of blood to the external surface, and to relieve the internal organs from the congestion and vascular distension which oppress them, and which, without such means, the vital powers might not be sufficient to overcome. The invasion of several maladies produced either by malaria, or by infectious emanations, or by moral or physical shocks, is often attended by vital depression, characterised by a sense of sinking and of coldness; by tremors, rigors, or shiverings; by failure of the pulse, as respects either strength or frequency, or both; by a shrunk, cold, and bloodless state of the external surface; and by a feeling of oppression or of anxiety at the epigastrium and præcordium. These phenomena, when they are caused by malaria, are in most cases soon followed by vascular and vital reaction, unless in those circumstances and cases which are fully described in their proper places (See Fever, Intermittent, &c. §§ 33—35.). — In the more severe and congestive of such cases, retching or vomiting is generally added to the above characteristics of vital depression; and when the invasion of infectious and pestilential maladies — of exanthematous and other fevers, produced by their specific poisons, is attended by signs of vital depression, such as, or similar to, those now stated, there are generally also superadded retchings or vomitings, or both, evincing the more serious nature of the vital depression, and showing the efforts of Nature, not only to throw off the morbid cause, but also to resist the impression it has made, and to overcome the congestion produced by it in the large vessels and vital organs. In such dangerous circumstances, nature points the way to the fulfilment of the indication under consideration, and therefore it should be followed by promoting it by appropriate means, such as by warm, stimulant, and demulcent draughts; by external warmth and warm baths, containing salt, mustard, &c., and by stimulating and aperient enemata, in order to remove fæcal accumulations and depressing morbid excretions. The great question is, In these circumstances how far should the vomitings be promoted or allowed to proceed? This can be decided only by the effects produced and, by the quantity and appearances of the matters ejected; but generally, if the retchings or vomitings continue beyond the time apparently sufficient for producing a salutary effect, if the matters thrown off be scanty, serous, or sero-mucous, and if the vomiting be attended by an internal sense of heat at the epigastrium, and tenderness or heat over the region of the stomach, and by other gastritic or gastro-enteric symptoms, then, instead of promoting the vomiting, or of exibiting stimuli, &c., the gastric irritability should be allayed by refrigerant or cooling demulcents, conjoined with sedatives; by external derivatives, and other suitable means. (See Art. Gastro-enteric Disease, and Stomach, Diseases of.) Nervous depression and sinking require for their removal the more diffusive stimuli, often conjoined with antispasmodics or with tonics, according to circumstances, and as shown in the article Debility (§§ 43, *et seq.*). The same symptoms which indicate the propriety of restraining retchings and vomitings, should also forbid the exhibition, by the mouth, of stimulants or tonics, which in other circumstances of vital depression, would be required, often liberally and frequently, but with due circumspection and regard to the effects produced, and to the peculiarities of the case; these

medicines also being selected judiciously, and according to an enlightened experience.

41. *C. Thirdly*, During our efforts to remove primary vital depression by suitable agents, due regard ought to be paid to the prevention of contingent or consecutive results of an unpleasant or serious nature; and when these cannot be prevented, they should be counteracted as far as possible. The internal congestions, which frequently occur during the vital depression directly produced by sedative infections and poisonous causes, frequently continue after efforts at reaction have been made; or, although partially removed, give rise to more or less disorder, especially when secreting or excreting organs have been thus affected. Not infrequently the viscera which experienced congestion during the primary depression, become, during the consequent reaction, the seats of a congestive inflammation or irritation. Hence the propriety of preventing or anticipating these results in the treatment employed to remove the primary morbid condition — of prescribing those means which are least likely to convert congestion into inflammation, and which, while they remove the depression, restore the vital manifestations in the several secreting and excreting organs, and promote the functions of these organs, especially of the skin, kidneys, and bowels. The contingent evils upon vital depression depend very much upon the depressing causes; and where these causes are specific, the effects are generally such as may be expected, yet they cannot be entirely prevented, or even always allayed or controlled. If the causes are concentrated, the susceptibility great, and the consequent depression extreme, the contingent congestion and consequent effects, although expected, may soon destroy life, however judicious the means which may be used. Numerous proofs of this are furnished us by the histories of the more malignant cases of remittent, continued, exanthematous, and pestilential fevers. In these the causes characterise the effects, and all the manifestations of these effects throughout the frame; but, although these effects necessarily result, well directed means may often allay or control them when they are excessive or dangerous. These means will necessarily depend upon the effects in the several forms of these maladies; and are such, as well as the particular effects they are employed to control, as can be discussed only under their specific heads, to which I must refer the reader.

42. ii. The Promotion of the several secreting and excreting Functions — of the depurating Processes, whenever they are torpid or impaired, has been just stated, as generally requisite to the prevention of many contingent evils, during states of vital depression by whatever cause produced; but it has a still more general application, for in all circumstances, and in all dynamic or other states of vital manifestation — in states of excitement and increased vascular action, as well as in those of depression — these functions are very often either torpid or impaired, or even interrupted, and require restoration; otherwise additional, or more severe and dangerous changes result, and the blood, loaded with excrementitial materials, occasions the most deleterious effects in vital organs. But the functions of depurating or excreting surfaces or organs are not confined to the mere elimination of injurious elements or materials. In connection with this depuration, the organic nervous fibriles, by means of the capillary vessels, affect more or less the state of the blood circulating in the capillaries, and impart to it a more complete organization as well as vital properties. The blood, in different parts of the capillary circulation — in the skin, in the respiratory mucous surface, in the digestive villous surface, in the structures of the several glands — by the influence exerted on it by the organic or ganglial nerves, through the media of the capillaries, thus varies, in vital properties and in sensible qualities, with the modified vital manifestations of the ganglia and their nerves; the functions of organs or parts owing not only their differences and specific characters to these modifications, but also the amount of their performance.

43. Next to the sedative or depressing effects produced by the causes of disease, the impairment or arrest of depurating functions closely follows, the latter being very frequently the consequence of the former. These functions are often, in these circumstances, restored by the same means as are employed to remove the primary morbid impression, especially by a judicious selection of emetics, and of diffusive stimuli, and by warm, hot, or medicated baths. In all cases — 1st. *The Causes which impaired or interrupted these functions should be ascertained and removed;* — 2dly. *The Means which the states of the several secreting and excreting fnnctions require for their due promotion, should be prescribed, and generally with marked reference to the causes on the one hand, and to associated and contingent pathological conditions on the other.*

44. *A.* Suppression of the depurating function of the *skin* illustrates the importance of these intentions, whilst it shows the several pathological effects which may result from it. The great diversity of these effects, upon different persons, depend upon,—1st. The existing susceptibility of the individual;—2nd. The amount and duration of the cause; — 3rd. The predisposition of certain organs or tissues to be affected; — 4th. The vicarious increase of other excreting functions, diminishing or modifying the effects produced by the cutaneous suppression;—5th. The concurrence of other causes with those which suppressed the action of the skin. The suppression of excreting function being referred to its cause with all possible precision, the exact nature and amount of the pathological effects should be ascertained. If the function of the skin be further considered in connection with this subject, we find that its suppression may be followed, especially if the kidneys do not perform a vicariously increased function, by catarrh, or by rheumatism, or by inflammation of the lungs or pleura, or by diarrhœa, or by dysentery, or by enteritis, or by other maladies, according as the predisposition of parts may determine the morbid action. The cause or causes, whether exposure to cold or to influences depressing vital power, occasion, first, interruption of the depurating function of the skin, and, next more or less fulness or congestion of, or vascular determination to internal viscera or parts; and, in addition to this latter effect, and as a consequence of the suppression of the cutaneous function, the blood is loaded with these excrementitious elements which the healthy action of the skin elimi-

nates. The conditions of the blood and of the circulation resulting from the changes and circumstances just enumerated, are such in many cases as kindle disease, either those now mentioned, or others of a slighter or severer nature. The practical importance of tracing the causes and the succession of effects is further illustrated by the beneficial results which follow, when these causes are duly recognised, and the means of cure judiciously directed to the removal of the causes and the effects produced by them, and especially to the restoration of the impaired or suppressed function.

45. Still further, the treatment of any of the diseases mentioned above (§ 43.), when occasioned entirely or chiefly by suppressed cutaneous function, is legitimately based on the principle of restoring this function, and by its aid of removing injurious excrementitious elements from the blood, of soliciting the circulation to the external surface, and of diminishing the vascular determination to the seats of disease. The importance of attending to the depurating function of the skin is too frequently overlooked in the treatment of diseases, and in health, by all classes of the community. In the cases to which allusion has been here made, the means commonly resorted to, viz. warm and medicated baths and diaphoretics, suited to the nature of the disease and to the existing states of vital power and vascular action, are those usually indicated. But the appropriate use of these is to be acquired only by close observation and by an enlightened experience.

46. Not merely the restoration, but also the due preservation, of all the functions are most essential both to the removal of disease and to the continuance of health — more especially of the excreting functions; and those performed by the skin are not the lowest in the scale of importance. There are several practices connected with this function, in health and in disease, that have been too much neglected in modern times, although adopted among the ancients, and even by uncivilized communities at the present day; these are, anointing the surface of the body with oil; oleaginous frictions of the skin, especially after bathing; and the use of woollen or cotton coverings for several diseases, and whilst having recourse to diaphoretics. Frictions of the external surface with oil,—with olive, palm, or other vegetable oils, promote the excreting functions of the skin, protect the surface from the injurious impression of physical, infectious, and morbid causes, and tend to preserve a due supply and distribution of blood to the extremities and external parts; and these effects are the more manifest the more constantly they are resorted to, in connection with due ablution and bathing. The advantages also which result from lying in blankets or other woollen coverings, during the exhibition of diaphoretics, or when the depurating functions of the skin are being promoted, have been too generally overlooked in modern times, and deserve adoption in many diseases requiring an increase of these functions.

47. *B.* What has been said respecting the promotion of the *functions of the skin* applies likewise to the *other secreting and excreting functions.* Impairment or interruption of these, caused either by depressed vital manifestation, by lost or paralysed power, or by mechanical obstruction, requires the same indications of cure as have been stated above (§§ 39, *et seq.*), due regard being had, in the selection of our means, to the remote and the more immediate causes, and to existing and contingent pathological states. Of all the excreting or depurating functions, those performed by the *kidneys* are the most important, and most rapidly fatal when impaired, interrupted, or suppressed. But it is not merely impairment of this function as to the quantity of the excretion, but disorder of it as to the natural quality that also requires attention. Both conditions demand close observation, and furnish important indications for the treatment of disease, these indications being always derived from pathological states of most serious import, whether existing at the invasion, or in the progress, or towards the termination of disease. Mere deficiency of this excretion may require the use of means — of *diuretics* — suited to the vital conditions and to the states of vascular action; but the quality or chemical constitution of the urine, either independently of quantity, or in connection with the abundance of the excretion, excites the most serious considerations, both as to the vital powers, and as to the states of the blood and circulation, and urgently requires powerful alterative or constitutional remedies, appropriate to existing pathological changes. Illustrations of the importance of recognising alterations not only in the quantity, but also in the constitution of the urinary excretion, and of founding rational intentions of cure on these alterations, are furnished in the Articles on the BLOOD, on DISEASE, on DIABETES, on DROPSY, on the exanthematous and continued FEVERS, on diseases of the KIDNEYS, on the URINE, &c., to which I must refer the reader for the intentions and means of cure, when the functions of the kidneys are impaired, disordered, or interrupted, as to either the quantity or the quality of the excretion, and for the pathological causes and the consequences of such disorders of this excretion.

48. *C.* Impaired and interrupted excreting functions of the *intestines* and *liver*, are next in importance to those of the kidneys. Many diseases originate in, or are characterised by, at an early stage of their progress, defective excreting action of the liver and bowels—in neglecting to promote these depurating functions. It is believed by many that the regular and daily evacuation of the bowels is quite sufficient; but this may not always be the case, as to either the fæcal discharge, or the biliary secretion, or even as to both; and, although the former may appear frequent and abundant, the latter may be deficient, or altogether wanting. Hence the importance of observing accurately the appearances of the intestinal excretions, both in health and in disease, and of having recourse to such means as those appearances, the frequency of evacuation, and the associated states of disease will suggest. The several substances arranged as *purgatives* and *cathartics* should be suited to the peculiarities of each case, and be conjoined with others of the same class, or with such as may either correct or promote their operation. The general effect of purgatives is to leave the bowels more or less torpid after their operation has ceased. This will often be prevented by conjoining a bitter tonic with the purgative, as a preparation of gentian, or of cinchona, with that of senna, or the sulphate of

quina with aloes, the digestive canal being thereby strengthened as well as excited to increased action. These and similar combinations are often slow in operating, but they generally procure full and feculent evacuations, whether given in these simple states of combination, or with various alkaline or saline and stomachic additions. The various topics connected with torpor or inaction of the bowels, and with similar conditions of the liver, — with impaired excreting functions of the liver and intestines, — are fully discussed under the heads, Cæcum, Colic and Ileus, Colon, Constipation, Intestines, Jaundice, Liver, Rectum, &c., to which my limits oblige me to refer.

49. iii. To equalize the vital and vascular Actions throughout the Frame is a practical object, desired in all diseases in which vital manifestation or vascular action is inordinately expressed in, or determined to, any particular structure or organ; or in which vital organs are congested or oppressed. The entire accomplishment of the two preceding objects generally also attains this. Yet states of disease sometimes present themselves, or circumstances occur, which induce the physician to prefer such means as more directly act in this way — which equalize the vital and vascular actions. Indeed, most of those means act also upon the secretions and excretions, more especially on those of the skin, as when warm baths, warm diaphoretics, pediluvia, &c., are prescribed; and the very agents which are given to restore vital power (§§ 37, *et seq.*) have often the effect of equalizing the circulation and promoting the secretions. The means just now mentioned generally produce these complex effects, and others are often equally efficacious when employed in suitable forms and appropriately to pathological conditions. The acetate and other preparations of ammonia, the spirits of nitric æther, sulphur, warm or imperfectly conducting bedclothes, warm diluents containing diffusive stimuli, &c., have similar effects. In cases where local determination, or increased flow of blood, occasions either oppression, or augmented function, or causes defect of function in parts from which the vital or vascular action is derived, not only those means, but others of a more strictly *revulsive* or *derivative* kind, are often required, especially local depletions, dry-cupping, blisters, rubefacients, and other agents, whose operation is more permanent or continued, as setons, issues, and similar modes of producing *counter-irritation*, or even suppuration and vascular discharges. (See Arts. Congestion, and Blood, *local plethora and determinations of*, §§ 23, *et seq.*)

50. iv. To moderate excessive Secretion and Excretion, or to restrain excessive Discharges, is an intention requiring much acumen in the physician, to carry into safe execution. For the secretion or discharge may not be safely restrained or stopped. It may be a safety-valve opened by nature; and, when this is the case, it should not be closed without another having been substituted. When an attentive and a discriminating examination of the case shows that the discharge is productive of injurious effects, and requires either to be moderated or arrested; and when it is associated with other disorder, equally requiring to be removed, then such means as will have this effect, consistently with the nature of the secretion or discharge and with the existing state of vascular action, should be employed. Whenever an excessive or unnatural discharge is attended by increased vascular action, attempts to moderate, and far less to arrest it, should not be prematurely or hastily made, or, if made, they ought to be directed chiefly to the states of vital and vascular action. A nasal or hæmorrhoidal discharge of blood may prevent an attack of apoplexy or palsy, or of congestion of the liver or lungs. Any chronic or prolonged discharge, if abruptly arrested, may be followed by congestion or inflammation of the affected organ, or of an adjoining part, or by effusion into a shut cavity. Thus I have seen the sudden arrest of a copious leucorrhœa followed in different cases by congestion of the uterus, by inflammation of this organ, or by peritonitis, followed by copious effusion of serum. The same effects may also follow sudden arrest of a too abundant catamenial discharge. Whatever merely suppresses the morbid effect whilst the pathological cause or condition is allowed to exist, may be productive of bad or even fatal results. A chronic diarrhœa, if suddenly suppressed, without due attention having been paid to the appearances of the evacuations, to existing pathological states, and to the excretions from the skin and kidneys, or without either establishing a free derivation from the bowels, or determining the circulation to the surface, &c., may be followed by enteritis or peritonitis, with or without serous effusion into the peritoneal cavity. Epistaxis, if prematurely arrested, especially in persons of middle or advanced ages, or full habit of body, may be followed by an apoplectic, paralytic, or epileptic seizure.

51. In all cases of excessive or prolonged discharge, the nature of the discharge, and the changes from which it proceeds, require attentive examination; and these particulars having been ascertained, the treatment should be directed chiefly to the changes producing it. Many inordinate discharges, especially when acute or severe, or of sudden occurrence, cure themselves. As soon as the irritating secretion or accumulated excretions are fully evacuated, the disorder ceases, as in many cases of autumnal cholera or diarrhœa, and there remains only a slight irritation, occasioned by the morbid secretions, which either subsides, or is soon removed by promoting the functions of the skin, or by correcting morbid tendencies in the blood and digestive functions, or by other suitable means. Recourse to the more powerful *astringents* or *tonics*, without due regard to the circumstances just mentioned, or is often had, in cases of excessive discharge, to others of equal importance connected with the source of mischief; and in consequence of the use of these, the disease is arrested, and the patient thinks himself cured. But, after a short time, a different disease is manifested, one often more serious than its antecedent, and proceeds without the cause of its occurrence being sometimes suspected. Hæmorrhoidal discharges, or fistula in ano, especially when chronic, have been followed at some period, more or less remote from their cure by these or other means, by congestion of the liver or lungs, by hepatitis or pneumonia, or by ascites, or by increase of pre-existing pulmonary disease, as is most frequently the case.

52. v. To moderate or allay existing ner-

vous Excitement, or unnatural Function, or irregular Action, is an intention which the physician is often called upon to accomplish, in the present state of society. The successful attainment of this end depends greatly upon a due recognition of the remote causes, both mental and physical, — both moral and corporeal, — and of pre-existing and existing changes. The removal of the causes should always be preliminary to attempts to allay the excitement, whether nervous or vascular. When the former is associated with the latter, it should always be ascertained whether the nervous disorder is occasioned by increased vascular determination and action, or whether this latter results from the former. The nature of the exciting causes will often render the procession of morbid phenomena more or less manifest, and at the same time suggest the indications and means of cure. When the causes are of a mental or moral nature, when they have acted chiefly on the susceptibility and sensibility of the individual, and when they have produced suffering, pain, spasm, or irregular muscular actions, then those means which are classed as *sedatives*, or *anodynes*, or as *anæsthetics*, are usually required; but in many of such cases, *stimulants*, or *antispasmodics*, or even *tonics*, may also be necessary in conjunction with these, particularly when debility or exhaustion is present. If, however, the nervous excitement be attended by increased vascular action, or local determination, and more especially if this excitement be a consequence of the vascular disorder, those means which will allay this latter disorder should precede a recourse to those which act chiefly on the nervous system. In such cases, the *antiphlogistic* and other measures usually required, are often aided by a judicious recourse to sedatives or anodynes, or even to anæsthetics or narcotics, especially when want of sleep, or excessive pain, or restlessness, or disordered muscular actions, characterise the affection. If the nervous excitement or disordered actions be traced to vascular determination to, or inflammatory action in, any portion of the cerebro-spinal centres or their membranes, or to a similar affection of the sexual organs, or to other inflammatory or febrile conditions, then the same indications and means of cure as are noticed in the following section (§§ 52, 53.) are necessary; and when they have been judiciously employed, they may then be followed by such of the medicines belonging to the above classes, as are most appropriate to the existing states of nervous disorder.

53. vi. To allay or moderate increased vascular Action, or to remove vascular Disorder, is obviously required, especially when excessive; for we cannot with propriety leave this disorder to the unaided efforts of nature, unless it be slight, and the constitution and age of the patient be such as warrant confidence in the result. In order to allay increased vascular or febrile action, the physician should investigate its causes, its manifestations, the states of the secretions and excretions, the indications of vital power, and the conditions of the circulating fluids, as far as they are indicated by the pulse and by the hue of the surface, of the lips and tongue, and of the extremities. The diathesis of the malady — sthenic or asthenic, dynamic or adynamic — and other changes having been inferred from these sources, the *indications* and means of cure must be based upon them. If the vascular or febrile excitement be *sthenic* — if it be characterised by a salutary reaction indicating neither impairment of organic nervous or vital power, nor contamination of the fluids — it should be allayed by the means classed as *antiphlogistic* and *febrifuge*, comprising blood-letting when the nature of the case requires it, in any form. In addition to these, substances which promote the secretions and excretions, which equalize the circulation when it is inordinately determined to particular organs, and which derive it from the affected organ to the external surface, are generally beneficial.

54. When the vascular or febrile excitement is *asthenic*, — when vital power is exhausted or depressed, and the circulating fluids are contaminated or poisoned by infectious or injurious elements, or materials which irritate or excite the vascular system, — then the *indications* of cure are: — 1st. To support the vital energies; — 2nd. To promote the secreting and depurating functions; — 3rd. To correct or counteract the morbid states of the blood, by such medicines as may be absorbed into the circulation and produce these effects. The importance of this last indication is so great as to require for itself a distinct consideration (§§ 54—56.). Sufficient illustrations of this therapeutical principle are to be found in the Articles Erysipelas, Fevers, Inflammations, and Pestilences, as well as under other heads, where a more special consideration is devoted to the several topics embraced by it.

55. vii. Morbid States of the Blood are to be corrected or counteracted by Means which Observation, Science, and Experience have shown to be suitable to this End. — Morbid conditions of the blood are so various as respects their causes, associations, and consequences, and are so little known, especially as regards their intimate natures and the slighter and subtiler alterations, as frequently to render the *intentions* of cure imperfect, their accomplishment unsatisfactory, and the choice and operation of means doubtful. We know that the blood and the secretions and excretions are more or less contaminated in many maladies, and owing to many causes, — 1st. That the contamination may take place slowly and insidiously, until, upon the action of some exciting or concurring cause, active disease is developed in the form of gout or rheumatism, or of scurvy, or of cutaneous affections; — 2nd. That it may result more rapidly and much more dangerously, owing to the absorption of morbid secretions or injurious materials into the blood, as in cases of purulent or sanious infection; — and 3rd. That it may take place in a more rapid and specific manner, from a poisonous infection, producing its peculiar seminium, and propagating itself amongst all who are susceptible of its operation, even although in may cases the changes of the blood are neither considerable nor manifest. Morbid states of the blood are often the most evident and productive of the most dangerous results in the advanced stages of continued, remittent, exanthematous, and pestilential fevers; and these states, whether proceeding from foul, contaminating emanations, or other causes, or from a seminium of a specific nature, generating its like, affect both the secreted fluids and the solids, as shown when treating of the

maladies produced by these causes. In the earlier stages and slighter cases of these diseases the changes of the blood are either very slight or not very manifest; yet they nevertheless may be inferred to exist, inasmuch as the odour of the blood has been found different, and the same species of disease has been propagated by it.

56. Alterations of the blood are owing, as shown above and more fully in the Articles BLOOD and DISEASE, and in those on the maladies in which these alterations are the greatest, to pre-existing morbid states, as in *scurvy, purpura, gout, rheumatism,* &c., or to the poisonous operation of infectious miasms emanating from a person similarly affected, as in the *pestilences,* the *exanthemata* and *malignant fevers.* We know, that diseases which are most malignant and dangerous, proceed from causes which remarkably depress the powers of life, and either suppress or disorder the depurating functions. Hence it may be inferred that, although the specific cause produces effects which are constant and specific, the resulting changes on the blood, especially when heightened by vital depression and impaired excretion, increase the malignancy of the malady, and often either occasion or hasten death. Now, to counteract these changes it becomes necessary —1st. To support, promote, or restore vital power, as far as may be possible; 2nd. To promote or restore the several excreting or depurating functions;—and 3rd. To endeavour to correct or neutralize the morbid materials or elements formed or accumulated in the blood in the progress of, or antecedent to the full development of the malady.—The *first* and the *second* of these intentions should be energetically carried out by the same or similiar means to those adverted to above (§§ 37—47.)—by powerful *restoratives, tonics, stimulants,* &c.; and by stomachic, warm, and stimulating *emetics, diaphoretics, diuretics,* and *purgatives,* as may be most appropriate to the nature and state of the malady.

57. The *third indication* is that which more especially concerns the present subject. In certain diseases, in which the blood is very manifestly altered, the crasis or coagulating power of this fluid is increased, as in rheumatism and gout; whilst in others it is more or less impaired, as in scurvy, and in the malignant maladies alluded to above. In the former, *alteratives,* as the alkalies and the alkaline earths, especially magnesia, are required to neutralize the acids formed in the digestive canal, and even also in the blood; in the latter, the most powerful *stimulants, tonics,* and *antiseptics,* are necessary to the restoration of vital power, of the irritability of the contractile fibre, and of the crasis of the blood, and to the counteraction of the tendency to dissolution manifested by both fluids and solids — to the putridity contended for by the older writers. Of the several tonics and stimulants often required to fulfil the present indication, it is unnecessary to make mention at this place, as their use is fully shown under the diseases in which they are most appropriate. Of those which manifestly prevent or counteract a septic tendency, it may be remarked that, whatever supports or restores vital tone, has indirectly this tendency, but that there are substances which possess this property in a more direct manner—that are more strictly *anti-septic,* as hydrochloric acid, the chlorides and hydrochlorides, chlorinated waters or fluids, the chlorate of potash, the nitrate of potash and several other alkaline salts, the terebinthinates, balsams and camphor, creasote and tar, the cinchona and cascarilla barks, and the barks of several trees, as the oak-bark, willow-bark, cedar-bark, &c. In the more urgent or malignant cases, two or several of these may be conjoined or given with stimulants or tonics, as the decoctions or infusions of cinchona, or of serpentaria, or of arnica, with nitrate of potash, the carbonates of the alkalies, or the chlorate of potash, &c.

58. viii. TO ALLAY MORBID IRRITATION BY MEANS SUITED TO THE SEVERAL MANIFESTATIONS OF THIS CONDITION is often of urgent importance, and always is attended by great difficulty, inasmuch as the successful accomplishment of this object requires an accurate interpretation of the cause and essence of the morbid conditions or changes on which the irritation depends. The source of irritation may exist *locally* in any structure or tissue, or in a nervous ramification; or generally, in the blood and in the secreted and excreted fluids; or both *locally* and *generally.* When it is *local,* it may, according as it may affect the nerves or the blood-vessels at its source, either occasion spasm, convulsion, or severe or neuralgic pain, or produce alterations of structure, acute or chronic inflammation, and their several consequences. When it is *general,* febrile action, more or less violent or acute — more or less rapid in its course, and dangerous in its issue — is always present; the morbid, contaminating, or poisonous materials present in the blood, and other fluids inordinately exciting vascular action, and at the same time depressing nervous or vital power. When the irritation commences locally and becomes general, then the secretions and nutrition of the part have been changed, and the morbid products have been absorbed into the circulation; and whilst the local irritation continues, the general irritation is superadded, occasioning an amount of febrile or general disturbance, varying with the nature and the amount of the materials absorbed, with the state of predisposition or diathesis, with the accumulation of these morbid matters in the blood, or with the rapidity of their elimination by the emunctories. Thus we have presented to our observation sources of local irritation and change, followed more or less rapidly by every grade of hectic or irritative fever; and not merely by these, but also by destructive changes consecutively produced in various organs, and more especially in those concerned in the elimination of the morbid matters from the blood. It is unnecessary to prosecute this subject any further, as it is fully considered in the Articles ABSCESS, ABSORPTION, HECTIC FEVER, and more fully and in its several relations, both pathologically and therapeutically in the article IRRITATION.

59. ix. TO ALTER, OR MORE COMPLETELY TO CHANGE MORBID STATES OF INDIVIDUAL TISSUES, OR OF THE STRUCTURES GENERALLY, may be considered an intention, the fulfilment of which is beyond our powers. I have shown, when treating of typhoid, adynamic, putro-adynamic, and malignant *fevers,* and *exanthematous* and *pestilential maladies,* and of *scurvy, syphilis,* &c., that we have every proof of alterations having taken place, in the advanced course of these dis-

eases, not only in the fluids, but also in the vital cohesion and intimate organisation of the more solid structures, and yet the vital powers may arrest these alterations, and gradually restore the healthy conditions. This great end can be attained only by the restorative efforts of nature — by the development of vital resistance to further changes. The constitutional powers often, by resisting further alterations, accomplish this object without assistance, or merely by the aid of freer ventilation, of a purer air, or by the removal of injurious influences. But these powers are often assisted or developed by art — by means which restore or promote nervous or vital energy (§§ 37, *et seq.*), and which moderate, correct, or remove morbid states of vascular action and alterations of the blood (52—56.). The indications, as well as the means, are fully discussed in the treatment of the maladies just referred to, and of several chronic and cachectic diseases, especially *scrofula, rickets, scurvy, venereal diseases*, &c., to which I must refer the reader.

60. x. To PREVENT OR REMOVE EXHAUSTION IN ITS VARIOUS FORMS is often required of the physician; but the nature of the previous excitement of which exhaustion is the consequence, should be ascertained, as the issue in many cases depends upon such excitement and its causes — whether mental or physical, moral or corporeal. The *indications* and the *agents* required to fulfil them, are usually the same as have been already mentioned when treating of primary depression of nervous or vital power (§ 37.). In this latter state of vital depression, although its cause may be more energetic and dangerous, yet the frame is more generally free from structural change of its tissues or organs, and reaction is more readily produced, than in the secondary vital depression, or exhaustion consequent upon mental, nervous, or vascular excitement. Whereas in the exhaustion thus produced, and more especially when following vascular disorder, alterations of the fluids, and even of the structures, are more likely to be present, and to complicate the vital depression, the structural change and the vital condition mutually increasing each other, often opposing the influence of the most judicious means of cure, and generally requiring the most energetic and the best-directed agents for their removal. The observations which I have offered on this subject when treating of *consecutive and complicated* DEBILITY (see Art. DEBILITY (§§ 43, *et seq.*) will further elucidate this subject.

61. xi. To REMOVE CONGESTIONS OF BLOOD, ACCORDING TO THEIR SEATS, is one of the most important ends for which medical aid is required: to accomplish this end the most energetic agents are often necessary, especially when congestion is complicated with marked depression of organic nervous or vital power, or with oppression or suppression of the functions of the congested organ. In these circumstances the indications are:— 1st. To *derive* the circulation from the seat of congestion to other external parts, by suitable *revulsants, rubefacients*, &c.; — 2nd. To equalize the distribution of blood throughout the frame, as advised above (§ 48.); — 3rd. To support nervous or vital power, especially when inordinately depressed, by appropriate restoratives and stimulants; — and 4th. To restore the function of the congested organ. This subject is fully elucidated in the Articles CONGESTION and BLOOD (§§ 23—33.).

62. xii. To ENABLE ORGANIC NERVOUS OR VITAL POWER TO RESIST THE SLOW EXTENSION OF DISEASE, OR TO OVERCOME ITS MORE RAPID ADVANCES, AND TO THROW OFF PARASITICAL AND OTHER FORMATIONS, are ends which should be much more frequently proposed for successful attainment in practice, than they usually are. In many diseases, the efforts of nature are insufficient for these purposes, unless they be aided by suitable means. In malignant and pestilential maladies, these efforts are inadequate in the most severe cases, and should be reinforced by the most energetic means, especially by tonics, stimulants, antiseptics, and others already noticed. In diseases of a slower course, as scrofula, scurvy, and morbid formations of various kinds, tonics, conjoined with alteratives, are generally indicated; but very much depends upon the choice which is made of these means, which should be appropriate to the nature of individual cases. In most of the diseases which require the development of vital resistance, restorative agents ought to be directed both to the organic nervous system, and to the blood — the energy of the former must be excited, and the crasis and purity of the latter must be preserved, or restored when deficient. In acute malignant maladies, the means which we possess are not always equal to the attainment of these ends. The vital energy may be too far depressed to be excited by medical agents, however well selected or directed; or, if it be excited, the reaction evinces features equally morbid and dangerous with those of the previous depression; for the states of the fluids, especially of the blood, conduce to structural changes as rapidly and certainly during vascular reaction as during vital depression. Hence it is generally insufficient merely to rouse the organic, nervous, or vital power, unless we also procure a free elimination of morbid materials or elements from the blood by the emunctories, and, at the same time, prevent or correct alterations of this fluid by means appropriate to the inferred alteration, as advised above (§§ 54—56.).

63. In chronic, malignant, or structural maladies, the constitutional or vital power is impaired, and the blood is altered more or less, although not always visibly or demonstratively altered. As these maladies advance, especially cancer, tubercle, rickets, &c., the alteration of the blood becomes more and more evident, this fluid being thinner, poorer, or deficient in red globules. Hence the necessity of supporting the powers of life by means which will neither excite nor irritate them, and of preserving the healthy state of the blood by conjoining with those means such as will correct or prevent alterations of this fluid, and will, at the same time, promote the conversion of the colourless or chylous globules of the blood into red globules — will promote the processes of sanguification and nutrition — as chalybeates and cod-liver oil.

64. The same indications and means which are most successful in resisting the slow extension of organic or malignant maladies, are also most advantageously employed in throwing off *parasitical animals* and *productions*, and in preventing their generation or formation. Although the expulsion of parasitical animals from the diges-

tive canal requires a recourse to a class of remedies which act chiefly either on the canal itself, or on the *entozoa*, or on both, and are usually classed as *anthelmintics*; yet the reproduction of these animals is to be prevented only by means which develope organic nervous power, which improve the states of the blood, and of the secretions and excretions, which promote the digestive functions, and which insure a healthy nutrition. Of these means nutritious food, and pure air and pure water, are amongst the most important.

65. xiii. TO RESTORE, AS FAR AS MAY BE RESTORED, IMPAIRED OR LOST FUNCTION is to remove a very large proportion of the ailments to which our frames are liable. This being a great end of medical treatment, the course which may be pursued in attaining it should be duly considered, and with a strict reference in practice to the nature of individual cases. The means used for attaining this object should be directed either — 1st. to the sources of function, — 2nd. or to the organ itself, whose function is impaired or lost, — 3rd. or to the promotion of the general health and constitutional powers, — and 4th. or even to these conjointly, coetaneously, or consecutively. — The great importance of attaining this object has been insisted upon, when noticing the consequences of impairment of the excreting, or depurating functions (§ 41, *et seq.*); but there are other functions than those of elimination which may be impaired, and the issue may be more or less serious. Most of the disorders comprised under the *first class* in the arrangement which I have followed in this work, consist of impaired function or defective action. And in all these the indications now stated may be severally adopted.

66. The means of cure, when not acting directly on the the surface or organ to which they are applied, and frequently even when directly effecting such surface or organ, act also — 1st. on the nervous systems, especially the organic, — 2nd. on the vascular system and on the blood; and through either or both these channels, indirectly or consecutively on the organs or surfaces whose functions are defective. The deficient function may thus be restored by stimulating the nervous endowment of its appropriate organ at or near the origins of the nerves; or by exhibiting medicines which are imbibed or absorbed into the circulation, and either alter the constitution of the blood or excite the organ or surface whose functions are impaired by their presence in this fluid. The actions of the kidneys, for instance, may be increased by stimulating applications over the loins, or by various substances (*diuretics*), which having passed into the circulation, and being carried by the blood to these organs, excite them to increased action, either whilst these substances are being eliminated by them, or whilst circulating through them before they are eliminated by some other emunctory. The secreting and excreting functions of the liver, of the digestive mucous surface, of the bronchial mucous surface, of the skin, &c., are augmented in similar ways, by the several classes of medicines, which, owing to these respective predominant modes of action, according to their doses and combinations, have been called *chologogues, aperients* or *purgatives, expectorants, diaphoretics*, &c.

67. xiv. TO PALLIATE URGENT OR DISTRESSING SYMPTOMS, EITHER WHEN THEY CANNOT BE REMOVED, OR IN ORDER TO OBTAIN TIME TO ASCERTAIN THEIR SOURCES AND FOR THE REMOVAL OF THESE SOURCES, OR PATHOLOGICAL CAUSES, is an intention which the physician may propose to himself either at the outset or invasion of disease, or at its ultimate or fatal close — even in cases of little or no danger, and in those of the greatest danger. It is obvious that the means, in these very different circumstances, should have strict reference to the nature and tendency of the phenomenon or symptom by which the patient is distressed. If it be alarming sinking, stimulants and restoratives are required; if violent or painful spasm, antispasmodics, anodynes, sedatives, &c. according to the seat, antecedents and concomitants of the *spasm*; if it be extreme pain, sedatives, narcotics and other means advised under the head of *neuralgic affections*; if to remove alarm or mental perturbation, the combination of restoratives or stimulants with sedatives or narcotics; making always such selection of means as experience, derived from enlightened and close observation, will suggest and will point out as appropriate to the features and complications of particular cases. A judicious application and combination of means, in the most extreme cases, and when no hopes of prolonging life can be entertained, will, in conjunction with the solace of religion, render dissolution as calm and peaceful as the accession of the natural sleep.

68. xv. TO EXCITE AND DIRECT THE MENTAL EMOTIONS, SO AS TO PREVENT THE EXTENSION OR AGGRAVATION OF DISEASE AND TO INSURE OR HASTEN RECOVERY, is one of the highest aims of medical science; and is often conducive both to the prevention and to the removal of disease. *Fear, anxiety*, and all the *depressing emotions* not only predispose the frame to the invasion of disease, but alas impart to disease an asthenic or low character, and conduce to unfavourable results; whereas, *confidence, hope*, and all the elevating emotions support the powers of life, reinforce the vital resistance, and impart a great share of the efficacy exerted by the means of cure. Not only ought all mental and moral circumstances which either have caused, or have influenced, the progress of disease, to be removed as far as possible, but the mind of the patient should be inspired with hopeful sentiments, and by the confident bearing and expression of the physician. There are numerous circumstances also directly affecting the mind, and indirectly influencing it through the media of the senses, which aid the treatment of disease, especially of diseases which are chronic, or which impair the mental energies. The chief of these are: agreable mental occupations; the solaces resulting from the performance of duties and from conferring benefits on the deserving; the contemplation of the numerous wonders and beauties of nature; the enjoyment of musical and harmonious sounds, of the appeals of reason and eloquence, and of instructive and interesting society; the affectionate regards of relations and friends, and rational amusements and relaxation. In addition to these, changes of scene, of air and locality, or more complete change of climate, and travelling, with all the circumstances which render travelling mentally and bodily healthful, should not be overlooked.

69. Having thus endeavoured to point out, for the *instruction* of the inexperienced, and as *suggestions* to others who wish to review the stores of information

with which observation may have enriched their minds, what I consider to be — 1st, *The fundamental principles of medical practice or Therapeutics*, — 2nd. *The more general principles*, — and 3rd. *The special principles of Therapeutics*, I shall conclude with an Arrangement *of the modes of employing*, and *of the operation of medicines*. When treating of Poisons, I gave a full exposition of the modes of exhibiting, the channels of operation, and the physiological and pathological effects of poisons. It is obvious that, as many poisons are employed, although in very different states and doses, as very important means of cure, the *classification* of these will necessarily approach to that of *Therapeutical Agents*; and hence several resemblances will be observed between the arrangement gives in that article and the classification which I am now about to submit to my readers.

Therapeutical Agents, Classification of, according to their Modes of Action and Effects.

The classification of medical agents is a matter of great difficulty, and hence numerous excellent attempts have been made to overcome the difficulty by many of the more recent writers on Therapeutics. My limits will not admit of my noticing these in the manner which they deserve; but the reader who is desirous of becoming acquainted with them, will find them in the works of their respective authors enumerated in the Bibliography. The arrangement I am now about to adopt, may not be superior to several of those which have been already published; but, as it is in accordance with the views exhibited in this work, more especially in this article, and in that on Poisons, I have adduced it at this place.

I. Psychical or Mental Remedial Influences.

i. Those furnished through the Media of the senses. — *The sensual affections of mind* — *External affections of mind.*

A. Affections of mind induced by *pleasant odours* and *tastes.*

B. States of mind induced by *vision* — by the sight of the beautiful in nature and art, of endeared objects, especially after absence or dangers, &c.

C. *Sounds* and *Noises*, of various kinds, especialy such as are monotonous, often favour the occurrence of sleep. — Appeals of reason and eloquence. — Musical and harmonious sounds, vocal and instrumental, in due variety or combination. — The society of relations and friends. — Rational amusements, &c.

D. The Sense of *Touch*: — Frictions — Rubbing — Shampooing — Flagellation, &c.

ii. The Intellectual affections of mind.

A. A due and moderate exercise of the powers of *perception* — *conception* — *memory* — or *powers of consciousness.*

B. A well directed exertion of *imagination* — — of *reason* and *judgment* — and of *other active intellectual states.*

C. A due exercise of the *powers* of *reflection* — of *right* and *wrong* — of *causation and truth* — of *duty* — *immortality*, &c. — of *rational incentives to duty.*

iii. The Moral Affections of Mind.

A. *Instinctive or simple moral affections.* — Hope — Confidence — Anticipation of pleasures and happiness — Love — Desire of approbation, of knowledge, of power, &c.

B. *Rational emotions of mind.* — The duties which the individual owes himself and those connected with him. — Religious obligations — Agreeable mental pursuits — Useful occupations — Rational amusements &c.

II. Hygeienic Agents and Influences.

i. Food and Drink.

A. *Food.* *a.* Vegetable and farinaceous aliments. *b.* Animal food. *c.* Mixed food. *d.* Regulated diet or dietetic regimen during and after disease.

B. *Drinks.* *a.* Distilled and spring waters. *b.* Mineral waters. *c.* Beverages, wines and liquors. *d.* Prescribed forms or combinations of these.

C. *Condiments* — Spices, Sauces, &c.

ii. Air and Locality.

A. *Purity of air*, in connection with locality with the soil and with its productions.

B. *Light and sunshine.*

a. Influence of light.

b. Effect of the sun's rays — the chemical — the electrical or magnetic — the colouring, &c.

c. Of the absence of either or all these.

C. *The Temperature, dryness, or humidity of the air.* — Dependence of these on latitutide, on altitude, on the soil, on the productions of the soil, on position or locality.

iii. Of Exercise.

A. *In-door exercise.* *a.* Occupations and employments.

B. *Exercise in the open air.* *a.* Walking. *b.* Riding. *c.* Active and athletic exercises.

iv. Climate and Change of Climate. — (see Art. Climate.)

A. *Climate of Great Britain and Ireland.*

B. *Foreign climate.* *a.* European. *b.* Asiatic. *c.* African. *d.* American. *e.* Australasian and Polynesian.

C. *Changes of climates.*

a. Effects of change on different races or colours.

b. Effects of change on disease.

D. *Travelling and Voyaging.*

a. Travelling by Railroads, or otherwise.

b. In sailing or in steam-vessels.

c. The several effects of these modes.

III. Medicinal Agents — Medicines applied to the Frame.

i. Modes in which Medicines are employed or exhibited.

A. *To the respiratory organs.* — Inhaled or inspired.

B. *Taken into the stomach.* — In various forms and combinations, without or with the food.

C. *Injected or introduced into the bowels.* — Enemata and suppositories.

D. *Introduced or injected into the sexual and urinary organs.*

a. Into the vagina.

b. Into the urethra and urinary bladder, &c.

E. *Applied externally.*

a. To the general surface, or part of the surface.

b. To a part of the surface after the removal of the cuticle. — Endermic medication.

F. *Injected into the blood vessels.*

ii. The Action of Medicines.

A. Locally and Primarily — On the tissues to which they are applied.

B. Remotely and Consecutively. — Sympathetically, and by the blood.

C. Both Locally and Remotely.

D. Chemically—By altering the chemical constitution of fluids and solids.

E. Mechanically and Surgically.

F. Vitally — By altering the states of function or vital manifestation.

G. Organically. — By affecting the structure or the intimate organization of parts.

ii. The Modes in which, and the Channels through which Medicines act.

A. Primarily and Locally.

a. On the nerves of the part.

b. On the capillaries of the part, and on the contained fluids.

c. On the irritability of the tissues.

d. On the organization and structures of the part.

B. *Sympathetically or through the media of the of the organic and the animal systems of nerves.*

C. *By imbibition, or endesmose and absorption.* Through the medium of the circulating fluids, especially the blood.

iv. The General Effects of Medicines.

A. Depressing nervous influence and vascular action.—Lowering vital power—Sedatives or depressants.

B. Stimulating nervous influence, either organic or animal.—Stimulants.

C. Exciting vascular action.—Phlogistics.

D. Exciting both nervous influence and vascular action—Excitants.

E. Exhausting nervous influence, or vital energy — Exhaurients.

F. Altering, otherwise than dynamically, nervous influence and vital power.—Alterants.

G. Changing the sensible appearances and the constitution of the blood.—Hæmapharmaca. Blood-Remedies,

H. Producing a succession of two or more of these effects,

Classification of Medicines according to their Special Operation.—The Physiological Action of Medicines.—*Remedial agents according to their special effects.*

Class I. Abstracting the Animal Heat, or depressing the Calorific Process in a part or throughout thr Body. — Refrigerants.

i. *External Refrigerants:* — Thin clothing—Cool or cold air—Cold Baths—Cold affusions or Douche—Cold sponging—Shower-baths—Cold or evaporating lotions—Ice applied externally —Cold solutions,

ii. *Internal Refrigerants.*

a. Dietetic Refrigerants.—Lemons, Oranges, Mulberries, Strawberries, Pomegranates, Confected Ices, Tamarinds, Common Sorrel, Lettuce, Whey, Butter-milk, &c.

b. Medicinal Refrigerants.—Cold fluids,— Ice and Iced waters—Solutions of hydrochlorate of ammonia—of Nitrate of potash —of Nitrate of soda—of most of the alkaline neutral salts—Citric Acid and the citrates—Tartaric acid and the tartrates—Acetic acid—Acetate of ammonia, &c.

Class II. Depressing, suppressing, or benumbing Sensibility, or paralysing, Involuntary and Voluntary Motions. — Sedatives.

i. *Mental Sedatives,* — Grief, Anxiety, Fear, Terror, Regret, Sadness, Disappointment, Loss of fortune, reputation, friends &c., Home-sickness, &c.

ii. *Physical or Medicinal Sedatives.* — Humid states of the atmosphere, and whatever favours the transfer or eduction of electricity from the frame. The preceding agents (Class I.) when long or largely employed, relatively to the state of vital power or resistance, The preparations of Lead and Saturnine Solutions, Hodrocyanic acid, Laurel water, Volatile oil of bitter almonds, Cyanide of potassium; Tobacco and its several preparations, especially the oil; the infusion, decoction, and smoke of Tobacco, Nicotina, Sulphuretted Hydrogen gas, Carburetted hydrogen gas, Carbonic acid gas, Chloroform and Æthers, especially when inhaled; excessive blood-letting, or vascular depletion causing syncope.

Class III. Softening, liquifying, or dissolving one or more of the Tissues or Textures.—Dissolvants.

The Alkalies and alkaline subcarbonates—Antimonial salts—The Oxalates and Oxalic acid—Boracic acid—Biborate of soda—Putrid animal matters, &c.

Class IV. Astringing the tissues, and increasing the Tone or Vital Cohesion of Structures — Astringents and Tonics. — Antiseptics.

i. *Vegetable Astringents.* — Oak-bark, Nutgalls, Catechu, Kino, Uva-Ursi, Rhatany, — Tormentilla, Pomegranate bark or rind, Logwood, Bistort, Matico.

ii. *Bitter Tonics.* — Quassia, Simarouba, Gentian, Calumba, Cheirayta, Common Centaury, Buckbean, &c.

iii. *Astringent and Bitter Tonics.*—The Cinchona Barks, Spigelia,, Elm-bark, Willow-bark.

iv. *Aromatic Tonics.* — Cascarilla bark, Wormwood, Elecampane, Canella bark, Angustura bark, Hops, Cedar bark.

v. *Acid Tonics.* *a. Mineral Acids:*—Sulphuric, Nitric, and Hydrochloric acids; Alum. *b. Vegetable Acids.* — Formic acid, Gallic acid, Catechuic acid.

vi. *Alkaloid Tonics.* — Quina, Cinchonia, Salicine, Quassine.

vii. *Metallic Tonics.*—The salts, oxides, and carbonates of iron, of silver, of zinc. The bichloride of mercury in minute doses.

Class V. Irritating Tissues, Structures, and Organs. — Irritants. — Corrodants.

i. *The mineral salts,* in large doses or in quantities above those producing a tonic or astringent action. The chlorides and chlorates of the alkalies. The metallic salts as the sulphates and chlorides of zinc, copper, &c. The Nitrate of Silver, salts of antimony, &c. Lime unslacked.

ii. Euphorbia, Croton Tiglium, Savine, Rhus Toxicodendron, Mezereon, Pyrethrum, and numerous acrid or irritant *vegetable productions* and vegetable oils. (See Art. *Poisons*, §§ 234. —248.)

iii. *Animal Irritants,* as Phosphorus, Cantharides, and the scales of many insects. Morbid Animal secretions and poisons.

iv. *Physical and Mechanical Irritants:* — Urtication, Heated air, Hot water, Heated metal. The Actual Cautery, Setons, Issues, &c.

Class VI. Relaxing the Tissues, or lowering the Irritability of Structures. — Emollients, — Demulcents.

i. *Aqueous Emollients:*—Water at ranges of temperature betweeen 65° and 170°. — Aqueous Vapour, Medicated Aqueous Vapours.

ii. *Mucilaginous Emollients—Demulcents:*—Prepared from gum Arabic, Tragacanth, Mallows, Marsh-mallows, Coltsfoot, Linseed, Sweet Almonds, &c.

iii. *Amylaceous Emollients:* — Farinaceous and starchy substances. Flour, Oatmeal, Barley, Sago, Arrow-root, Starch, Tapioca, &c.

iv. *Sacharine Emollients:* — Honey, Liquorice, Sugar of Milk, Beet-root.

v. *Albuminous Emollients:* — White and yolk of eggs, Milk, Saliva.

vi. *Gelatinous Emollients:* — Gelatine in its pure or other forms, or as obtained from Isinglass, Hartshorn shavings, Tendons, Bones.

vii. *Oleaginous Emollients:*—Animal fats, Butter, Spermaceti, Vegetable oils, especially Palm, Olive, Almond, Linseed, and other oils.

Class VII. Stimulating, or exciting the Vital Manifestation of a Tissue or Organ. —Stimulants—Excitants.

Stimulants are related, on the one hand, with *Tonics* and *Irritants*, especially when the latter are given in small doses; and with *Sudorifics*, *Evacuants*, and *Diureties*, on the other. They act primarily on the organic nervous, and on the Cerebro-spinal nervous Systems, according to the manner of using them.

i. *Condimental and Aromatic Stimulants.*—Garlic, Leeks, Onions, Mustard, Horse-radish, Scurvy-grass, Water-cresses, and other anti-scorbutic plants. The hot or warm Spices:—Ginger, Pepper, Capsicum, Cloves, Cinnamon, Canella, Ginseng, &c.

ii. *Resinous and Balsamic Stimulants:* — Guaiacum, Mastic, Elemi, the Turpentines, Copaiva, Opobalsum, Benzoin, Styrax, Tolu, Peruvian Balsam.

iii. *Gum-Resins* ; — Assafœtida, Ammoniacum, Galbanum, Sagapenum, Opoponax, Myrrh, Olibanum.

iv. *Camphoraceous Stimulants:* — Camphor, Arnica, Serpentary, Contrajerva, Valerian, Cajuputi oil.

v. *Ammoniacal and other Stimulants:* — The preparations and Salts of Ammonia. The empyreumatic oils, Phosphorus, Musk, Sumbul, Castor.

vi. *Alcoholic Stimulants:* —The several alcoholic liquors. Wine, Alcohol, the Æthers. Malt and fermented liquors.

vii. *Calorific and Electrical Stimulants.* — A temperature exceeding 60°. The sun's rays, especially as imparting light, heat, and electrical influence. Dry heat above 60° and not exceeding 120°. The electro-motive or the electro-magnetic current.

Class VIII. Augmenting the Secretions and Excretions—Evacuents—Depurants.

Substances which produce this effect, generally first excite the organic nerves, supplying the parts on which they act, and consecutively attain the end which chiefly characterizes them. In larger doses, they not only stimulate the functions to which they are directed, but often also *irritate* more or less remarkably the tissues to which they are applied. They are thus closely related to *stimulants*, and to *Irritants* and *Alterants*.

i. *Increasing the Secretions from the Schneiderian membrane. — Errhines.*
  a. *Aromatic Errhines:* Lavender, Marjoram, Sage, Spices, &c. reduced to powder.
  b. *Acro-Sedative Errhine:* — Tobacco, Euphorbium, Veratrum, Asarum, &c.

ii. *Augmenting the salivary Secretion—Sialagogues.*
  a. *Local sialogogues — Masticatories:* — Mezereon, Pellitory of Spain, Horse-radish, Ginger, Betel nuts, Betel leaf, Mustard, Tobacco, &c.
  b. *Remote or contingent Sialogogues:*—Acting through the medium of the circulation:—preparations of Mercury, of Iodine, of Gold. Foxglove, Hydrocyanic acid, Nitric acid, &c., in rare instances.

iii. *Provoking the discharge of the contents of the Stomach, and increasing the secretions from its villous surface. — Emetics. — Vomits.* — The biliary and pancreatic secretions are also frequently increased by the operation of emetics.
  a. *Vegetable Emetics:* — Ipecacuanha, Tobacco, Mustard, and other vegetable irritants, taken in large doses.
  b. *Mineral Emetics:* — Emetic Tartar, Sulphate of Zinc, Sulphate of Copper.

Of these Tobacco and Emetic Tartar are the most despressing: often so depressing as to be injurious or even poisonous. They ought never to be given in states of vital exhaustion or Narcotism.

iv. *Producing Alvine evacuations.—Purgatives—Cathartics:*—
  a. *Laxatives or Lenitives, Mild Aperients:*—Manna, Cassia pulp, Tamarinds, Prunes, Almond and Olive Oils, Magnesia, Bitartrate of Potash.
  b. *Cooling Antiphlogistic or Saline Purgatives:*—The Sulphate of Soda, Potash and Magnesia, Citrate of Magnesia, Tartrate of Potash.
  c. *The Milder Purgatives:* — Sulphur, Senna, Rhubarb, Aloes, Castor Oil.
  d. *Chologogue Purgatives. Alterative or Mercurial Purgatives:* — Calomel and other preparations of Mercury. Bitartrate of Potash in large doses.
  e. *Drastic or Acrid Purgatives. Hydragogue Cathartics:* — Jalap, Scammony, Gamboge, Black Hellebore, Colocynth, Sulphate of Potash, Elaterium, Croton oil.

v. *Promoting the Excretion of Urine — Diuretics:* — Acting chiefly through the medium of the Blood.
  a. *Acid and Saline Diuretics:* — The dilute Mineral and Vegetable Acids, the Carbonates of the Alkalies, the Vegetable Salts of the Alkalies, especially the Bitartrate and the Acetate of Potash, the Citrates of Soda, Potash, and Magnesia, the Nitrates of Potash and Soda.
  b. *Irritant Diuretics:* — Squills, Common

Broom, Cantharides, Juniper, Turpentines, and Balsams.

c. *Sedative or Depressing Diuretics :* — Digitalis, Colchium, Tobacco.

d. *Alcoholic and Ætherial or Stimulant Diuretics :* — Dilute Spirit, Gin, Ale, the Nitric and other Æthers.

vi. *Promoting Cutaneous Transpiration. — Diaphoretics.*

a. *Diluent or aqueous Diaphoretics :* — Warm Fluids, Whey, Tea, Gruel, Broths, &c.

b. *Saline, Antimonial or Cooling Diaphoretics :* — Acetate, Citrate, and Carbonate of Ammonia; Alkaline Citrates, andTartrates, Nitrate of Potash, Sulphur, Sal Ammoniac, the preparations of Antimony, weak solutions of Camphor.

c. *Opiate Diaphoretics :* — Opium, Morphia, and their preparations, conjoined chiefly with Ipecacuanha, or with one or more of the foregoing, or with the Æthers.

d. *Warm or stimulating Diaphoretics :* —The preparations of Ammonia, Sassafras, Mezereon, Guiacum, Camphor in full doses, Spirits or Alcoholic fluids, the Ætherial preparations, Coffee.

vii. *Promoting the discharge from the Bronchi and Trachea.—Expectorants.*

a. *Vapours inhaled into the Lungs ;*—The dilute vapour of Turpentine, or of Tar, or of Creasote, or of Camphor, or of Iodine, or of Benzoic or Acetic Acid ; the smoke of Stramonium, or of Tobacco.

b. *Stimulating Expectorants ; acting chiefly by the Organic nervous system and the Blood :* — Camphor. The Gums and Gum-resins, the Balsams, Ammoniacum, Squills, Senega, Garlic, Onions, Sulphur.

c. *Nauseating or emetic Expectorants —Depressing Expectorants :* — Preparations of Antimony, of Ipecacuanha, Lobelia inflata, Tobacco.

viii. *Exciting the Catamenial Discharge—Emmenagogues.*

a. *Purgative Emmenagogues :*— Acting chiefly on the lower Bowels. Aloes, Camboge, Colocynth, Calomel, Black Hellebore.

b. *Diuretic and stimulating Emmenagogues :* — Savine, Juniper, Rue, Cantharides, the fœtid Gums, Castor, the preparations of Iron, Myrrh, &c.

d. *Acting more directly on the Uterus :* — More frequently restraining hæmorrhage from the uterus by exciting contractions of its parietes, than favouring a discharge from it. Ergot of Rye, Biborate of Soda, Oil of Turpentine.

Class IX. Exciting the Cerebro Spinal Nervous System — Nervous and Muscular Excitants.

Nux Vomica and Strychnia, and plants containing Strychnia, Brucia Antidysenterica, Coculus Indicus, Coriaria Myrtifolia, &c. &c.

Class X. Irritating and depressing Medicines—Irritating and paralysing.—Acro-Sedatives. Substances which irritate the Tissues and depress organic nervous or vital power.

i. *Mineral Acro-Sedatives :*—Arsenic and its compounds. Tartar Emetic and Antimonial preparations. Cupreous substances: Baryta and its Salts; Sulphate of Potash in large doses, Oxalate of Potash, Chromate of Potash, the Sulphurets, Tartaric Acid.

ii. *Vegetable Acro-Sedatives :* — Aconite and its preparations. Colchium autumnale, Helibore and its species, Digitalis, Indian and Virginian Tobacco, Castor Seeds, Jatropha Manihot, Veratria, &c.

Classs XI. Irritating and Alterative—Acro-Alterant Medicines.

i. *Mineral Acro-Alterants :* — Chlorine and the the Chlorides. Chlorate of Potash, the Hypochlorides: Iodine and its compounds, Iodide of Iron, of Mercury, of Arsenic, Bromine, Mercury and its preparations, Arsenic, &c. The Alkalies.

ii. *Vegetable Acro-Alterants :*—Iodine, Bromine, the Thorn-apple, Conium, Belladonna, Benzoin, Camphor, Turpentine and the Terebinthinates and Balsams, Tar, and Tar Water.

Class XII. Altering Vital Actions.—Alterants—Deobstruents :—Changing the state of the secretions, and of the nutrition of certain textures and organs, according to the substance employed, and the mode of employment.

i. *Mineral and Metallic Alterants.*—Sulphur, Magnesia, the Carbonates of the alkalies, the Preparations of Iron, of Mercury, of Iodine, of Arsenic, &c.

ii. *Vegetable Alterants :*—Taraxacum, Carbon, Sarzaparilla, Sassafras, Citric acid and Citrates ; the preparations of Iodine, especially the Iodides.

iii. *Animal Alterants :*—Cod and Torsk liver oil, Ox-gall.

Class. — XIII. Stupefying or narcotising the Nervous Systems.—Narcotics.—Hypnotics. — Anæsthetics.

i. *Gases and Vapours, especially when inhaled :*— Carbonic acid gas, Carburetted hydrogen gas, Sulphuretted hydrogen. The vapour of Chloroform, or of the Æthers, or of Alcohol.

ii. *Vegetable Narcotics :*—Opium, Morphia, and their preparations. The smoke of Opium, Henbane, Cicuta virosa, Poppy, Hops, Hemlock-dropwort, Lollium temulentum, Canabis Indica (an uncertain narcotic).

Class XIV. Affecting the States of the Blood and Capillary Blood-vessels Hæmato-cathartica.—Hæmapharmaca.

i. *Altering the Appearance and Condition of the Blood. Blood-medicines :*—The Alkaline Carbonates, Magnesia and its citrate, the Nitrate, Citrate, and Chloride of Potash ; the Chlorate of Potash ; the Nitrate, Citrate, and Chloride of Soda ; Chloride of Sodium ; Alkaline Solutions, Sulphur, weak or dilute Acids, Chlorine and Chlorinated solutions and waters, Nitro-hydrochloric acids, Citric acid. The preparations of Iron ; Chalybeate and Mineral springs and artificial mineral waters.

ii. *Constringing the Capillary blood-vessels and altering the state of the blood circulating in them :*—The Mineral acids, the diacetate of lead, the spirits of Turpentine, the Ergot of Rye, the Gallic and Tannic Acids, Matico, Creasote.

Class XV.—Inducing Contractions of the Uterus.—Parturifacients.—Parturients. Ergot of Rye, Biborate of Soda, Spirits of Turpentine, in full doses or in enemata.

Class XVI. Expelling Worms and Preventing the Formation of Worms.—Anthelmintics.

i. *Mechanical Anthelmintics* :—Filings of Iron, Granular Tin, Cowage, *&c.*, followed by drastic purgatives.

ii. *True Anthelmintics* :—Substances poisonous to parasitic animals :—Oil of Turpentine, Tar and Tar water, Creasote, Animal oil or Dippel's oil ; Chenopodium or worm-seed, or its oil ; Spigelia or Pink-root, Male fern, bark of Pomegranate root, bark of the root of Azedarac, Fucus helminthocorton, Corsican Wormweed, Tanacetum vulgare, common Salt, Kousso.

iii. *Purgative Anthelmintics* ; — Calomel, Jalap, Scammony, Castor oil, Aloes, Hellebore. — Most efficacious when following the exhibition of the preceding.

iv. *Medicines preventing the formation of Worms* :— Assafœtida, Myrrh, the preparation of Iron, Tar-water, Charcoal ; Quassia, and bitter tonics.

Class XVII. Preventing or correcting a Tendency to a Dissolution of the Tissues, or to a Solution of the Vital Cohesion of Textures—Antiseptics.

The Substances classed as *Astringents* and *Tonics* (Class IV.) are also more or less *Antiseptic.*

i. *Mineral Antiseptics* :—The Chlorides of the alkalies, the Hypo-chlorides, Chlorine and Chlorinated fluids, the Chlorides of the metals and of the metalloids, the Tincture of the hydrochloride of iron, the Chloride of Zinc, the Mineral Acids.

ii. *Vegetable Antiseptics* :—Tar, Turpentine, Tar water, Creasote, Charcoal, Camphor, the astringent and tonic Barks, Quina, Beebirine, Tannin, Gallic, and Gallic Acids.

Class XVIII. Neutralizing Acidity, removing or preventing Antacids. — Sorbefacients.

i. *Direct Antacids* ;—The Alkalies and Alkaline Carbonates, the Carbonates of Iron, of Zinc, of Bismuth, Magnesia, Lime and their Carbonates, Lime-water.

ii. *Indirect Antacids* :— The Mineral acids, Tonic and Bitter Infusions, Tonic Mineral Salts, Sulphate of Quina, &c.

Class XIX. Destroying or removing, or counteracting an infectious Seminium or Miasms. — Disinfectants.

i. *Destructives* :—Heated air from 180° to 254°. —This is the only real disinfectant. All other substances, which have been extolled as disinfectants, act merely by *removing* offensive odours, or by *fortifying* persons exposed to infection against its invasion. The medicines enumerated in Classes iv. vii. and xvii., by increasing the vital tone and cohesion of the tissues, enable the body to present a greater or less resistance to the impressions made by infectious miasms, and in this they are aided by mental excitement and confidence, and by the several stimulants and tonics, when these are so employed as not to be productive of consecutive exhaustion.

In the above attempt at classifying Therapeutical Agents, I have departed far from previous arrangements. Certain *Classes* or *Orders* have been created, whilst others have been omitted : of the former there is little to be remarked, and that little will be seen by the reader who is acquainted with the subject. I have omitted the *Class, Antispasmodics,* because there is really no class of medicines which possesses the property of directly arresting spasm ; substances which have acquired this appellation, possessing their only claims to it by their contingent action on the morbid conditions productive of spasm. Some writers have created a class of *Revellants* or *Counter-irritants.* But revulsion, or counter-irritation, is merely the employment of means comprised in Classes v. vii. and viii., in such a manner as to induce irritation and consecutive vascular determination to parts at a distance from the seat of morbid action, or to solicit an increase dflow of blood to viscera or organs, by promoting or exciting their functions. It will be perceived that I have arranged several substances under more than one class. This necessarily follows the varying and even different action of the same substance, according to its dose and modes of exhibition or combination. For very enlightened views as to the operation and classification of Therapeutical Agents, I may refer the reader to the more recent works on Therapeutics and Materia Medica, enumerated in the Bibliography.
